### Encouraging Signs in Atlantic Markets

An encouraging sign in the New York situation is the number of inquiries by large consumers. Confidence is slowly increasing and with general business showing signs of greater activity it is expected that actual buying will soon set in. Reserve stocks are slowly fading. Accumulations at tidewater range between 1,100 and 1,500 cars daily, more than sufficient to meet current requirements and in some instances too large to prevent some buyers from picking up bargains when shippers find it necessary to sell coal to avoid demurrage charges.

Buying at Philadelphia is increasing but spotty, the orders being small. Big buyers are still holding off, but expect to be in the market soon, as general business is picking up. Prices remain on about the same level.

Despite the persistent dullness a note of optimism pervades the Baltimore market. Inquiries are not brisk and spot purchasing is at an extremely low ebb, but the trade is encouraged by reports from various industries that conditions are slowly but surely improving. Another lull has come to the export movement, only one ship having cleared during the past week.

Some improvement is being shown at Birmingham, but progress is slow. Orders are somewhat more plentiful for steam fuel in the open market and consumers are taking to contract making in greater numbers. However, there is no great amount of room for optimism as far as actual business booked is concerned, but the undertone is unmis-

takably healthier and more hopeful and steadily increasing activity is expected from now on. Production for the week of Aug. 9 was 326,000 net tons, showing a fair increase over the previous week, but there has been no improvement in working time at the mines. The iron market is very dull and foundry coke is in a rather quiet position with quotations \$5 @ \$5.25 per ton ovens for 72-hour product.

### Independents Heavily Booked for Hard Coal

Activity in the New York hard-coal market is largely confined to independent coals, which for the most part are quoted below company schedule. The exception is stove coal, which is quoted by some of the smaller operators at slightly above company schedule, especially when taken straight. Many independents are heavily booked for future delivery and some are refusing quotations for immediate delivery. Stove coal continues to lead in demand, some retail dealers complaining of inability to obtain sufficient to meet the demand. However, most buyers are willing to take a share of their order in either egg or chestnut if assured of the other size. Pea coal moves slowly and operators find it difficult to keep their tonnages moving. There are no favorable signs in the steam-coal situation. Buckwheat No. 1 continues the weakest, while barley appears to be the best seller.

Signs of improvement continue in the Philadelphia anthracite trade, mostly in the retail trade, where the dealers report an increase of small orders. The larger companies still maintain a four-day schedule, but they all hope to make full time during September. Stove coal continues to be the size the dealer wants if he asks for anything at all. Nut and pea are plentiful with all shippers. Steam coals have not improved, although there are faint signs that better movement is likely to be in order soon.

A number of Baltimore anthracite dealers report better ordering. Practically all have liberal stocks on hand and they are delivering as quickly as orders are placed. Coal men are urging consumers to take fuel now, pointing out that prices will undoubtedly advance about 25c. Sept. 1.

Buffalo consumers are buying a little better now. Canadian buyers, however, are far behind their usual outlay.

### Not Much Activity in Coke Market

There has been little actual market activity in the past week in the Connellsville coke market, but general conditions show a slight improvement in the outlook. The operators are all firm at \$3.25 for furnace coke except for a few that hold out for still more. Foundry coke has been still duller in the past ten days, but the market is unchanged, at \$4.00 to \$4.50. The *Courier* reports coke production in the Connellsville and Lower Connellsville region in the week ended Aug. 16 at 16,300 tons by the furnace ovens, an increase of 100 tons, and 33,320 tons by the merchant ovens, an increase of 3,200 tons, making a total of 49,620 tons, an increase of 3,300 tons.

Foreign Market  
And Export News

British Market Subnormal but Steady;  
Output Hard Hit by Holidays

The Welsh steam coal market continued steadier though holidays have interfered with production and the volume of business is anything but satisfactory. The progress made at the Inter-Allied Conference has encouraged buyers abroad and the pressure for supplies has shown a slight increase. French inquiries are better, Italian business is fair, and South America is taking more coal than during the last two months. Supplies are limited owing to the number of collieries that are closed because of the unremunerative prices, the latest stoppage being the large Cambrian collieries. The better grades of coal are firmer, other sizes are plentiful and cheap. The market position is regarded as increasingly serious.

The Newcastle market remains very quiet except for some improvement in the gas coals section. Many collieries are still closed down, some are on short time, and several are being operated on a day-to-day basis, according to the amount of business received. The Amsterdam gas works has taken 30,000 tons of gas coals, and has placed another order for 30,000 tons in Germany at a lower price. The Lithuanian Rys. have placed an order for 30,000 tons at 28s. 6d. per ton, the class of coal not stated. Northumberland coal hewers will undergo a reduction of 9d. per shift this month on account of the June audit.

The output of the British collieries during the week ended Aug. 9, a cable to *Coal Age* states, was 3,446,000 tons, according to the official reports. This compares with 5,010,000 tons during the week ended Aug. 2. The decline in production was due to the observance of the holiday week.

July exports totaled 5,487,889 tons as compared with 6,767,255 tons a year ago. Exports for the first seven months of 1924 amounted to 36,618,946 tons, which is 10,000,000 tons below the figures for the corresponding period of

1923, or 21 per cent reduction this year. This decline was caused by lower shipments to Germany, the Netherlands, Belgium and France.

Trade Slack at Hampton Roads;  
Outlook Lacks Promise

The Hampton Roads market shows little or no change from last week, prices remaining almost the same and tonnage dumped continuing in about the same volume. The Norfolk & Western piers dumped 157,000 tons during the week, and indications were that during the coming week the tonnage would pick up.

Shipments to South America continue to be the outstanding movement, cargoes moving out regularly. Returning ship masters assert that Rio de Janeiro is being stocked with American coal.

The three railroads handling coal at the Roads report business slack with prospects of only small increases, if any, in tonnage.

French Domestic Coal Active;  
Industrial Grades Quiet

Little change is observable in the French coal market, industrial fuel being quiet while house coals are animated and even active; but even in the case of the former stocks are not very important.

Imports from Great Britain are rather weak, buyers holding back owing to the instability of exchange and the prohibitive prices for anthracite grades. Sales of sized coals are few for the present time. Free offers for German coals, outside of indemnity deliveries, are now being made on the Paris market.

The O.R.C.A. was supplied with 39,522 tons Ruhr coke from Aug. 1 to 5, or a daily average of 7,904 tons. Deliveries continue to decline at the re-

quest of French industrialists, impelled by financial considerations on one hand, and lack of room to store supplies on the other. No change in price is foreseen for the present.

The M.I.C.U.M. agreement between the German mine owners and the Franco-Belgian Commission in the Ruhr regarding industrial operations and the making of deliveries in kind by the Germans for the reparation account has been extended until Sept. 23.

## News Items From Field and Trade

### ALABAMA

The Sloss-Sheffield Co., of Birmingham, recently placed with the Link-Belt Company, of Chicago, an order for a gondola car dumper. This dumper will be similar to that installed at the Cahokia power station, East St. Louis. The new machine will be required to dump gondola cars of coal of a capacity of 100 tons at the rate of twenty an hour. Only a 19-hp. motor and one man are required for its operation.

According to a statement from John T. Cochrane, president of the Alabama, Tennessee and Northern R.R., with headquarters in Mobile, three surveys recently have been made for a proposed line from Reform, Tuscaloosa County, through Walker County to connect with the St. Louis & San Francisco R.R. at or near Fayette. If this line is built it will afford an outlet to valuable coal fields in Walker County not now served by transportation facilities and will provide a direct short route to the Gulf. It has not been definitely decided that the line will be built or which route it will take if it is constructed.

### ALASKA

Wood as fuel is being replaced by coal at a number of Alaskan mining properties in the Fairbanks region as a result of the development of a well equipped mine on the Healy River. The property is operated by the Healy Coal Corporation. The quality of the coal is described as good. The main haulway now has been completed for distance of 1,100 ft. It is timbered, lagged and muddilled throughout. A new power plant has been installed and electric units to operate the mine on the most economical basis. Sizing equipment also has been installed. This coal also is replacing wood for domestic use in a wide territory along the upper end of the railroad.

### COLORADO

Union mine officials, in a letter to the State Industrial Commission, charge the Bell Mining Co., operating in the northern Colorado coal fields, with making an unauthorized cut in wages. The union officials assert that the company, without authority, reduced wages from \$8 to \$7 a day. The management of the company verbally denied the charges, maintaining that the cut was made in accordance with an agreement made with the Mine Workers when the company took over the properties, May 1. Under terms of the agreement, the management says, it was agreed to pay the same scale in effect at the Eureka

mine, another company working. This scale provided for \$7 a day.

### ILLINOIS

Frank F. Tirre has been appointed general manager of the Mulberry Hill mine of the St. Clair Coal & Mining Co., at Freeburg, and also in charge of sales, with headquarters in the Fullerton Bldg., St. Louis.

In these times of despondency in the coal trade it is unusual in Illinois to learn that coal leases are being taken up, for which reason much surprise has been occasioned by the activities of agents purporting to represent the Crawford Coal Co., of Chicago, who have been leasing acreage in eastern Williamson County, along the Illinois Central R.R.'s Edgewood cutoff.

Railroad building in the Franklin County coal field would seem to indicate an early pick up in the coal industry. The Illinois Central is planning a switch from a point between Benton and Logan to mines Nos. 1 and 2 of the Chicago, Wilmington & Franklin Coal Co., also tapping mine No. 18 of the Industrial Coal Co. at West Frankfort. The Missouri Pacific R.R. will build from half way between Buckner and Benton to mines Nos. 1 and 2. Trains at these mines will be made up as the coal is loaded and a "Joint-road" locomotive will deliver the "trains" to each of the four trunk coal carriers, the Illinois Central, the Missouri Pacific, the Burlington and the C. & E. I.

Richard J. O'Halloran, a coal miner, of Spring Valley, has announced his candidacy for president of the State Labor Federation. "The interests of labor require the entire time of its leaders," says O'Halloran. "In the present campaign John Walker, president of the state Labor Federation, and his group of co-workers devote about 80 per cent of their time working in behalf of Governor Small's re-election. And while the officialdom of the state labor federation is working for Small the interests of 40,000 unemployed coal miners in the state are neglected. Most of these miners don't know where the next meal is coming from." According to O'Halloran he has been promised the support of the state miners and a number of large Chicago unions. The nominations will be held this month and the election in December.

The Lovington Coal Co., successor to the Lovington Coal Mining Co., was organized at a meeting held at Lovington, Aug. 12. The new company starts with more than half of the capital stock of \$100,000 subscribed for on the first day. Old stockholders of the

company which went into bankruptcy, to the number of probably 125, attended the meeting and were given the first chance to subscribe for stock in the new company. At the receivers sale, the old company was sold to George Spitler, acting for a group of the stockholders, for \$5,000, recognized as a nominal price for the property, which represented an investment of a half million dollars and which had paid dividends during the life of the company to the total amount of \$300,000. Directors of the new company were elected as follows: J. A. Vent, Hammond; E. L. Beall, Decatur; R. E. Bowers, Lovington; Daniel Hall, Dement; John Benson, Decatur; George Spitler, Mt. Zion; D. W. Beggs, Decatur. A meeting for the election of officers and for general organization will be held soon.

### INDIANA

The Triangle Coal & Coke Co., Auburn, has reduced its capital from \$25,000 to \$10,000.

Work in the new Deep Vein coal mine, three miles south of Princeton, was resumed recently after it had been shut down for several months for the installation of new equipment. The present force consists of fifty men, but this will be increased as soon as rooms are opened up on the two main entries. The mine is electrically equipped. It is situated on the Chicago & Eastern Illinois R.R. E. J. Smith, of Terre Haute, is president of the company.

Improving conditions in the Indiana coal fields are reflected in the resumption of operations by the McClelland Coal Co., at its mine south of Terre Haute after several months' idleness. Two hundred men have returned to work and within a short time from 50 to 100 more men will be placed at work there. Several of the larger mines in the Terre Haute-Clinton field and in the field south of Terre Haute have resumed operations in the last few weeks, sending many miners, who had been idle for several weeks, back to their work.

Governor Branch has named twenty-one delegates to represent Indiana at the American Mining Congress to be held in Salt Lake City, Utah, Sept. 29 to Oct. 4. The list of delegates is as follows: William Johnson, Vincennes; Harvey Conrad, Bicknell; James Moore, Evansville; Harry Sherburne, Terre Haute; Clem Richards, Terre Haute; Frank A. Kattman, Terre Haute; Richard Thomas, Universal; Norman McClevey, Petersburg; John A. Templeton, Terre Haute; Homer Talley, Terre Haute; Duncan McDill,

Clinton; Ed Shirkie, Terre Haute; W. G. Spears, Terre Haute; George T. Gillson, Universal; John Sieffert, Terre Haute; L. M. VanArsdale, Sullivan; T. I. Roberts, Terre Haute; John Ellison, Winslow; John Oglivie, Bicknell; W. E. Cox, Francisco and H. P. Dyer.

## IOWA

Increased consumption of fuel mined in Iowa to the exclusion of foreign mined coal was urged at a meeting of miners and union officials at Des Moines Aug. 11. Lawrence Love, representing the mine operators, and John P. White, former international president of the mine workers, urged an active campaign to convince householders of the state that it is to their interest to burn Iowa coal. George Baker, head of the farmers' union, pledged the help of the farmers of the state to the movement of the miners. Joe Morris, president of district No. 13, United Mines Workers, and John Gay, secretary of the district, declared the officers and district board would co-operate with the local miners.

## KANSAS

A. C. Ellsworth, who as a member of the Ellsworth-Klaner Coal Co. thirteen years ago pioneered steam-shovel coal mining in the Pittsburg field and more recently has been directing the affairs of the Ellsworth Coal Co., has sold his Pittsburg residence and announced that he will dispose of his coal interests. Mr. Ellsworth will move to Chicago, where he has real estate and other property interests. The Ellsworth company has two large steam-shovel mines near Minden, Mo., in operation and recently acquired a tract of coal land near Bronaugh, Mo.

W. C. Ernhart, superintendent of the Central Coal & Coke Co. mines in the Pittsburg field, resigned, effective Aug. 15, to take a position with an Indiana coal company. He is succeeded by Roscoe H. Reid, who had been assistant superintendent. Mr. Reid entered the

employ of the Central twenty-two years ago as a clerk. The Central operates four large shaft mines and a shovel mine in the Pittsburg field and has a large unworked acreage. It has recently acquired large tracks in Craig County, Oklahoma, adjoining the Kansas border, and will soon develop it. The office of assistant superintendent will be abolished with the promotion of Mr. Reid to the superintendency.

## KENTUCKY

Abner Lunsford, who has charge of the Henry Ford mining interests in West Virginia and Kentucky, when in Cincinnati recently, said that he was so well satisfied with the movement to the Ford coal roads, boats and upper lakes docks that he had given orders to run the Pond Creek Coal Co.'s properties on full time.

The Gatliff Coal Co., of Williamsburg, has increased its capital stock from \$75,000 to \$375,000.

Fire starting in the boiler room of the Norton Coal Mining Co., at Empire, Ky., in Christian County, on Saturday night, Aug. 16, destroyed tippie, boiler room, a loaded gondola, and put the mine out of operation.

J. W. Ailstock has resigned as assistant superintendent of the Youngstown Sheet & Tube Co.'s Rum Creek No. 5 mine, at Dehue, Logan County, W. Va., and is now mine superintendent of the Weeksbury mines of the Elkhorn Piney Coal Mining Co.

Five men were reported to have been killed in the mines of the United States Coal & Coke Co., near Harlan, Ky., on Aug. 18. Three men were crushed to death in a slate fall, a fourth later from injuries received in the fall, while a fifth man was electrocuted in another company mine.

The rapid development of strip mining in Kentucky is shown at Centertown, Ky., where the Morrison Coal Co. is reported to be loading around

600 cars a month, and the Kershaw Mining Co., around 1,000 cars a month. The Dawson Daylight Coal Co., near Dawson, the newest and largest strip operation, has had its first cars set in and has just completed its shovel and equipment, and was reported to be starting operations this week. This mine is on the new Central City-Dawson Springs extension of the Illinois Central R.R., which will be in full operation for its entire length in October.

An order has been issued by Judge A. M. J. Cochran of the U. S. Court of the eastern district of Kentucky for the sale of three mining properties of the Jewett, Bigelow & Brooks group in southeastern Kentucky. As soon as the legal requirements can be met receivers E. L. Douglas and Harry Ritchey have been ordered to sell the properties of the Hazard Jellico Coal Co., the Black Joe Coal Co. and the First Creek Coal Co. All of these are in the Hazard district. The receivers have been handling the properties for about three months.

Tax assessments of five coal companies in Pike County and one in Hopkins County were certified to W. H. Shanks, Auditor of Public Accounts, and to the County Courts by the State Tax Commission. All make considerable raises, Commissioner Wells said. The assessments in Pike County: Edgewater Coal Co., \$577,592; Big Sandy Co., \$1,225,010; Consolidated Coal Co., \$1,028,167; Colony Coal & Coke Co., \$393,610; Fordston Coal Co., \$2,975,028. The St. Bernard Mining Co., Hopkins County property was valued at \$2,393,497.

## MINNESOTA

Bids were opened last week by the City and County Board of Control in St. Paul for furnishing coal for the county poor farm and for the Ancker city hospital. The low bid for the hospital for 2-in. Indiana screenings was that of the North Western Fuel Co., St. Paul, at \$5.15 delivered, while the C. Reiss Coal Co. was low for Hocking screenings at \$5.60. For the county home, the M. A. Hanna Coal Co. was low for 2-in. Indiana screenings at \$4.60 and the Northwestern Fuel Co. for Hocking screenings at \$5.15.

## MISSOURI

The miners' union and coal operators of the Fulton district have reached an agreement on prices for the next fiscal year, the miners setting a price of 8c. a bushel for mine run and 9c. a bushel for screened coal. Contracts on this basis are being signed.

## NEW YORK

Sealed proposals will be opened by the Superintendent of Lighthouses, Staten Island, N. Y., 2 p.m., Sept. 2, 1924, for approximately 1,800 tons of bituminous coal in quantities as required during October, November, and December, delivered and trimmed into vessel's bunkers under contractor's coal chute, New York Harbor. Information upon application.

Courtesy U. S. Distributing Corp.

### Seams of Mammoth Thickness Are Found in Wyoming

This scene is in No. 45 mine of the Sheridan-Wyoming Coal Co., at Monarch, Wyo. The height of the topping is almost as great as the depth of the car from upper edge to car bottom.

Coal dealers docking their barges at the municipal docks in the City of New York will have to pay an increase of about 1c. per ton if the new wharfage rates proposed by Dock Commissioner Michael Cosgrove become effective. The proposed rates show practically a uniform increase of 100 per cent above the existing schedule and, according to Commissioner Cosgrove, will be the first general revision since 1870. The new rates propose a charge of 1c. a running foot with a minimum charge of \$1 for boats transporting coal docking at bulkheads or unshedded piers. For boats docking at shedded piers the charge will be 2c. a running foot, with a minimum charge of \$2.

## OHIO

The receivers of the Maynard Coal Co., Columbus, have appointed A. L. Allais, of Chicago, manager of their eastern Kentucky properties in the Hazard field. Two of the mines use Lennut, as their shipping point, the third, Heiner. Mr. Allais has been authorized by the receivers to make all repairs necessary for the immediate opening of the three operations and it is expected that within the course of the next week or so the mines will be running again. Mr. Allais is president of the Columbus Mining Co., with headquarters in the McCormick Building, Chicago, operating four mines adjacent to the Maynard properties in the Hazard field. The Columbus Mining Co., will market the output of the Maynard properties.

## OKLAHOMA

The strip pit of the Pine Mountain mine at Heavener is installing machinery costing \$250,000. A steam shovel equipped with electric lights, so that it may be worked night and day, is a feature. A specially constructed shovel for loading coal also is to be installed. A rotary dump and cars of 5 cu.yd. capacity have been purchased. The tipples will be equipped with a scraper line conveyor which takes the coal from the rotary dump hopper to the shaking screens, where the different sizes will be separated, and then to the 40-ft. loading booms and dumped in freight cars. An 18-ton dinky engine will furnish power.

## PENNSYLVANIA

Pennsylvania State College will start in the autumn a new optional course for students desiring special training in coal-mine engineering.

The two big mines of the Mather Coal Co., at Mather, Greene County, which had been closed for six months, resumed two weeks ago with the expectation of producing about 9,000 tons daily by the end of the week.

The Scotch Valley mines, near Mt. Grove, between Berwick and Bloomsburg, will soon resume operations and 200 men who have been out of work since last December will be put on their old jobs. Work on the new \$100,000 breaker to replace the one burned during the strike last December is being rushed and it is expected that the plant

will be ready for the preparation of coal early in November. The new breaker will have a capacity between 600 and 800 tons of coal a day.

The Buckeye Coal Co. has resumed 75 per cent activity at its mine at Nemaquin, ten miles east of Waynesburg, Greene County. Its first day's production was 2,500 tons, but it expects to have full production of 5,000 tons daily by Sept. 1, with the completion of a skip shaft. The mine had been closed since June 4.

Many workers who left the anthracite fields during the suspension of 1923 and located in New England cities and towns are returning because of industrial conditions, employment agents report. There has been some retrenchment in the hard-coal collieries, but it is predicted they will be operated on full time soon. Some of the small mines have been closed or workers have been laid off on account of a drop in demand for the steam sizes of fuel.

The British Government has shipped to Pittsburgh half a ton of its permitted explosives, which will be tested by the Bureau of Mines.

Maderia, Hill & Co., of Philadelphia, owners of several large anthracite-producing mines, have purchased the Buck Ridge Colliery near Shamokin. The mine has been shut down since last December, when the Buck Ridge Coal Co., which formerly operated the mine, was forced to ask for a receivership. The new owners have issued orders for a resumption of work. The colliery, during normal operation, gives employment to 400 men.

M. R. Campbell and W. T. Thom, of the Geological Survey, have been doing geological work in the Lykens Valley region of the anthracite field.

## UTAH

The Oregon Short Line Ry., which maintains large offices in Salt Lake City, will construct a line to the Brown Bear coal mine in Teton County, Idaho.

Two noteworthy tipples are now under construction in the Utah coal fields, each of which represents an investment of more than \$200,000. The United States Fuel Co. is erecting a five-tracker at Hiawatha which should go into service this autumn and the Spring Canyon Coal Co. is about to erect one at its Storrs mine. Both tipples, especially that at Storrs, will be equipped to supply the latest refinements of coal preparation.

## WEST VIRGINIA

Fire of unknown origin on Aug. 12 caused "several thousand dollars" damage in the Putney mine of the Campbells Creek Coal Co., Putney, according to M. V. Rensford, general manager.

The Super Fuel Co. is being formed by O. Proelss and others at Moundsville, W. Va., with a capital stock of \$100,000, about \$40,000 of which has been subscribed by the officers of the Franklin Coal Co., of West Virginia. The contract for the erection of a plant at which the sulphur will be separated from the fuel part of coal has been

awarded to the Pittsburgh Super Fuel Co. and the new plant is to be ready for operation some time in December. The plant will employ about 200 men. O. Proelss will have charge of the new plant.

With a view to building three miles of railroad from Henlawson to the mines of the Merrill Coal Mines, Inc. in Logan County, the Little Creek Railroad Co. has been organized with a capital stock of \$400,000. Active in organizing this company were C. V. Jones, F. M. Livezey, S. S. McNeer, J. F. Eaton and M. L. Burnett, all of Huntington.

## WYOMING

A. J. Collier has mapped the Buffalo anticline in Sweetwater County for the U. S. Geological Survey.

P. J. Quealy, head of the Kemmerer Coal Co., of Kemmerer, was originally slated to be one of the committee which formally notified John W. Davis of Clarksburg, W. Va., of Mr. Davis' nomination by the Democratic party for the Presidency of the United States. Mr. Quealy was slightly indisposed, however, and did not go East.

## CANADA

J. F. Soward, of the John Soward Coal Co., of Kingston, Ont., has returned from Scotland, where he purchased a new steamer for the lake coal trade. The boat, which was built in Glasgow, has arrived at her dock in Kingston.

James Smith, of Edmonton, has been appointed by James Murdock, Federal Minister of Labor, chairman of the board of conciliation to investigate the dispute between the operators and men in the Edmonton coal field. R. J. Drinnan will represent the operators and P. J. Rowe the employees.

## New Companies

**The Mender-Patton Coal Co.**, Nelsonville, Ohio, has been incorporated, with a capital of \$10,000, by William Patton and E. D. Mender.

**The Martins Ferry Coal Co.**, Martins Ferry, Ohio, has been incorporated by J. D. Hall and Lenora Boyers. The company has a capital of \$10,000.

Articles of incorporation for the **Medicine Lake Coal & Clay Co.**, in Sheridan County, Montana, have been filed with County Clerk and Recorder Verne Johnson. The location is section 16, township 32 north, range 55 east. Headquarters will be in the town of Medicine Lake. Capital stock is listed at \$100,000, the three directors being R. P. Jones, of Medicine Lake, T. H. Class and John O'Boyle, of Billings.

**The Cornelius Coal & Mining Co.**, Vincennes, Ind., has been incorporated with a capital of \$25,000. The directors are: James H. Cornelius, Homer L. Oliphant and A. J. Marks.

**The Kentucky Coal Distributing Corporation**, Evarts, Ky., capital \$10,000, has been chartered by W. B. Smith, O. H. Wood and W. C. Turner.

**The Barnett Fuel Co.** has been incorporated in Kansas City, Mo., with a capital stock of \$25,000, by Max Barnett, David R. Derge and Alton Gumbiner, and has opened headquarters in the Gloyd building.

**The Cass Coal Co.** has been incorporated at Cass, Ind., for the purpose of prospecting for coal and clays. The incorporators are: Charles Arthur, Charles Scammehorn, Earl Cox, Jesse Daniels and William Thompson.

## Traffic News

### Recommends Revised Rates from Colorado and New Mexico

The Colorado & New Mexico Coal Operators' Association was upheld by Examiner Koebel, of the Interstate Commerce Commission, Aug. 18, in its contention that the rate structure on coal, including anthracite, bituminous and lignite, was unreasonable and prejudicial and preferential to competing coal-producing districts of other states. The complainants operate coal mines in Colorado and northern New Mexico and sought a revision of rates on coal in carloads to Missouri River points and destinations in western South Dakota, Nebraska and Kansas.

Examiner Koebel recommended a revision of the present rate structure to the commission.

### Rate Boost by C. & O. Suspended

Proposals of the Chesapeake & Ohio Ry. to increase the westbound rates and reduce the eastbound rates on bituminous coal, carloads, moving between stations in West Virginia, north of Belva, were ordered suspended by the Interstate Commerce Commission Aug. 22. Pending an investigation by the commission the carrier's proposals have been suspended from Aug. 25 until Dec. 23 next.

## Obituary

**"Dutch" Bowling**, superintendent of the Cardiff Pocahontas Coal Co., of Lexington Ky., was killed near Bluefield, W. Va., on Aug. 13, when his auto was sideswiped by another machine, causing Bowling's machine to plunge over an embankment into Tug River, death being instantaneous.

**Edwin Thomas**, identified for years with the iron and coal industries in the Lehigh Valley, Pennsylvania, died Aug. 17, at his home in Catasauqua, Pa. He was president of the Pioneer Mining & Manufacturing Co., of Birmingham, Ala., before that concern was taken over by the Republic Iron & Steel Co. Mr. Thomas was 70 years old.

**Charles Oliver**, 68 years old, of Paonia, Col., a retired mine operator, died in Pueblo, Col., recently. He was a pioneer resident of Colorado, having gone to that state in 1879. He leaves his widow, Mrs. Mary Oliver, of Paonia; a brother, Alexander Oliver, of Alamosa, Col.; a son, Curtis L. Oliver, and two daughters, Mrs. C. D. Hailey, and Mrs. E. T. Morgan of Maywood, Ill.

**Dover Williams**, 50 years of age, brother of John W. Williams, well known Knoxville (Tenn.) operator, and himself active in the Harlan (Ky.) fields for a number of years, died at Fountain City, Tenn., Aug. 15. He was an assistant to K. U. Meguire in Harlan County for some years as superintendent of the Lick Branch Coal Co., lessee of the Harlan Coal Mining Co., of which K. U. Meguire was president. For years he was active at Harlan and Coxton. More recently he had been in charge of mining operations at Summitt, Ky., for a rock asphalt company. A widow, son and two daughters survive.

**William D. Walbridge**, coal operator and authority on bituminous coal mining, died Aug. 8, funeral services being held Aug. 10, at his home in Shrewsbury, N. J. Mr. Walbridge was president of the Pulaski Anthracite Coal Co. and the Delparin Anthracite Briquet Co., having retired from the presidency of the American, Kentucky Block and other coal companies. He was born at Toledo, Ohio, in 1856, a son of the Rev. Henry B. and Helen Chase Walbridge, his mother being a sister of the late Chief Justice Salmon P. Chase. His wife, formerly Mary Southwick, of Albany, and a daughter, survive.

## Coming Meetings

**New York State Coal Merchants Association, Inc.**, 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**American Chemical Society.** Fall convention Sept. 8-11, 1924, at Ithaca, N. Y. Secretary Gas and Fuel Section, O. O. Malleis, the Koppers Co., Pittsburgh, Pa.

**Oklahoma Coal Operators' Association.** Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

**Association of Iron and Steel Electrical Engineers.** Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 N. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Device Keeps Boiler Water At Fixed Level

To keep water in a boiler at any given level the Cooperative Utilities Co., 1014-15 Harrison Building, Philadelphia, Pa., has provided a feed-water regulator, both simple and practical. When the water rises in the water column to the level of a small pipe, steam ceases to flow through the pipe to a small tank, which weighs empty about 12 lb. and full of water about 32 lb. When the stream is thus shut off,

### Feed-Water Automatically Regulated

The float-like tank fills with water when the water is high and so falls pushing up a valve on the other end of a lever. This shuts off feed.

that which is already in the tank and pipe condenses and the water is forced from the column up the pipe and into the tank. The tank is suspended from a lever TW at T, a counterweight being hung at W and the fulcrum being at A. When, owing to the increased weight of the tank, it descends lifting the counterweight, it raises the stem B of the balanced valve in the feed line and thus shuts off the flow of water to the boiler. As soon as the water in the boiler drops, the water flows out of the small tank, steam taking its place. The tank is thus made light and the counterweight accordingly falls pulling down the stem of the balanced valve and thus restarting the flow of water to the boiler. Thus the water is kept at a constant level.

### Frees Boiler from Scale And Keeps Itself Clean

Pure distilled makeup water enables boilers to be run without scaling, makes boilers efficient in operation and enables them to be run without being blown off or shut down for repairs. Equipment known as the G. R. Bentube Evaporator has been placed on the market by the Griscom-Russell Co., 90 West St., N. Y. It has self-scaling heating tubes widely spaced which carry steam through the evaporator and vaporize the raw water in the shell. These tubes being bent distort with temperature changes and effectively crack off accumulated scale.

The tubes being fully submerged give the heating surface maximum efficiency, prevent superheated vapor, the baking

**Bentube Evaporator for Makeup Water**

When water is used again and again, efforts spent in keeping the little water clean that the boiler requires to replenish its losses, result in great boiler efficiency. The bent tubes in this evaporator buckle when heated, break off the scale and keep clean and pervious to the heat of the steam passing through the tubes.

of scale on the tubes and the formation of corrosive gases. Ample room is provided for the removal of accumulated scale at the bottom of the shell. The heating surface is sloped for the

free drainage of condensed steam. The tube bundle consists of a series of independent vertical sections, each easily removable for inspection. The shell and vapor dome are of welded steel plate.

### Unusually Small and Light Watt-Hour Meter

A new service type of direct-current watt-hour meter has been placed on the market by the General Electric Co. This meter is much smaller and lighter in weight than the present type. In addition to its reduced size and weight, other outstanding features are a thin cast alloy back or base; bottom con-

**Small Direct Current Meter**

nections with separate terminal compartment and removable terminals, and the same damping magnets and register as used on standard service type alternating-current meters, together with armature and shunt field

coil similar to those used in a previous type.

### Primer for Steel Surfaces

A new paint known as Dixon's Red Lead-Graphite Primer recently has been placed on the market by the Joseph Dixon Crucible Co., of Jersey City, N. J. For over a year this product has been under test by practical painters and has been found to meet the most rigid requirements.

Flake silica-graphite, red lead and a high-grade oxide of iron make up the pigment of this paint. The vehicle is boiled linseed oil. This primer will thus dry under normal conditions in about 22 hr.

It has been the design in making this paint to combine the desirable qualities of red lead with the water-repellant characteristics of silica-graphite. In application both the drag on the painter's arm and the wear on the brush are less than where straight red lead is used. Furthermore, this product will not chip or scale off, has greater covering power than red lead and is appreciably cheaper. It thus

### Semi-Closed Worm Box

These units are constructed so as to take any of the standard size worms made by this company.

meets the needs of those who desire to use a red-lead paint as a primer.

### Permissible Locomotive Has Approval of Bureau

The Bureau of Mines, has approved as permissible for use in gaseous mines a storage-battery gathering locomotive built by the Mancha Storage Battery Locomotive Co., St. Louis.

The locomotive has single-end control and has a single motor with worm drive for each axle. Its weight complete is from 7 to 8 tons. The same type of headlight, headlight switch and headlight fuse compartments are used on both locomotives. The motor on these locomotives was made somewhat larger than formerly was used for the same weight, and the capacity of the resistance has been considerably increased. The new controller is more

**Approved Battery Locomotive**

readily accessible than the one on the first locomotive built by this company and approved by the Bureau. The casings of the main three-way fuses have an insulating liner with greater clearances inside. The ampere-hour meter is housed in an explosion-proof casing and is insulated from the casing.

The motor, controller, resistance, main fuse box, headlight, headlight switch and headlight fuse box and ampere-hour meter housing were judged to conform to the requirements established for testing storage-battery locomotives for use in gaseous mines.

### Housing Takes the Thrust In Either Direction

A double-thrust worm box has just been placed on the market by the W. A. Jones Foundry & Machine Co., of Chicago. It provides an accurate and rigid support for the worm shaft and holds a liberal supply of oil in which the worm operates. Finished thrust washers are provided at both ends of the worm. They consist of two steel and one hard fiber washer placed in the center. The bearings are babbitted and faced on the ends. These boxes are now made in standard sizes to suit the standard-cut steel worms made by this company. These boxes are recommended for use with open worm-gear drives when something less expensive is demanded.

## Not Being Sure, Be Careful

STATIC electrical charges of rather high voltage are sometimes generated by leaks in steam and air lines. These charges are equalized by sparks jumping from the charged cloud of steam or atmosphere near the leak. Such discharges or so-called sparks may be several inches in length and even though of static origin conceivably might ignite an explosive mixture of gas and air. We are not too sure yet that no static discharges or mechanical sparks will ignite methane, and it is well still to act cautiously lest in a gassy mine, where compressed air or steam is used to the exclusion of all electricity, fire, or explosions may be caused by steam or air leaks. There is only one reasonably safe procedure: Do not allow an accumulation of gas in any place at any time.

## Better Mines, the Only Hope

WITH the proposed issue of the Dominion Coal Co. of \$15,000,000 in securities, and with the visit of George S. Rice to the mines of the company, the public is assured that the British Empire Steel Corporation does not intend to have its subsidiary meet the present low prices with inaction. Some companies have done this. One cannot commend their action. Most of them are up and doing, realizing that coal mining is not going to continue in the old rut but is going to have a renaissance.

We are unwilling to admit that coal mining is an unprogressive industry. It has made wonderful progress in recent years, but the next decade is going to see an accelerated movement, and those that lag behind soon will have to drop out of the race. The walk is going to change to a dog trot and the dog trot to a run in the next few years. The railroad industry is merely becoming more efficient, but the coal operator is not only handling recent equipment more effectively, but is reaching out for new methods. Some are sending men to Europe to see what the mines of that continent may afford.

## Canadian Competition

DESPITE the newness of Canadian coal enterprises—excluding in this reference those of Nova Scotia and perhaps Vancouver Island—the nearness of the seams to the surface, the opportunity to select which bed to work and which to reject, the price of coal at the mine is not low in Canada. Alberta coal, which Mr. Geddes in a recent issue deplored was not driving out coal from the United States, sold at the mine in 1922 and 1923 for an average price of \$4.07 and \$4.12, respectively. It would seem that the Albertans with their exceptional coal beds might blame themselves

rather than the railroads for any failure to drive out competing coals.

The Nova Scotia field is old and has extremely difficult circumstances to overcome, and that may explain why in 1922 and again in 1923 it realized an average of \$4.42 for its coal. New Brunswick received \$3.75 and \$3.90, respectively. Another section with great difficulties is British Columbia, its average price being \$5 and \$4.98. The Yukon price in 1922 was \$10 for its small production. Only Saskatchewan, with its lignite field, has low prices. It realized \$2.10 in 1922, and \$2.09 in 1923. The prices in the United States for bituminous coal in these years were \$3.02 and \$2.85. They have dropped since that time to \$2, as *Coal Age* price index shows.

The hope for Alberta and the other provinces of Canada is in more machinery, larger tonnage per plant and per day, and simplification of operation. Neither in politics, polemics nor in feverish recriminations but in industrial efficiency lies the real future of Canada.

## One Meaning for Every Word

ELECTRICAL engineers have a well-defined, exact nomenclature for their industry. No one has any doubt as to what the words used by an electrical engineer mean, provided one knows the technique of the industry. This favorable situation has not happened by chance. The technicians have met together and decided on the meaning of certain words.

The result is not wholly fortunate. The words are exact but there are no synonymns, with the result that good electrical literature is somewhat bald, and repetitions of the same word are inevitable. Moreover, it does not improve with time. We still use such awkward expressions as "alternating current" where we might use some abbreviated form without descending to the use of initials.

Furthermore, electrical engineers in general use awkward verbs. A motor "burns up" or "out" rather than "burns." Why it should "burn up" or "out" no one knows. There is nothing particularly upward or outward in the burning. It may burn down or in, but the engineer insists on the motor burning the other way whether or no.

Nevertheless the standardization of the words the electrician uses is of great help toward a comprehension of his meaning, and it would be well if the mining industry were to attempt a similar standard, drawing from its wealth of words liberally so as to use them all, simply limiting their meaning. Then we would have synonymns that would make the language flexible. We could draw from all our mining regions, from all those of England, Scotland and Wales, perhaps also from those of France, Germany and Mexico, and get a well-rounded nomenclature that could be written fluently.

If need be a few words could be invented to suit modern needs.

Our glossaries are of little use. They tell us all the corrupt usages of mining terms and do not indicate any preference in favor of one or the other usage. We need authority back of our technical dictionary—arbitrary authority if necessary. Then we would know just what is considered the best usage and cease to use the words for other purposes. Thus "gob" is used to express a place where the coal has been extracted and filled with refuse or a place which might be so filled without detriment, if room were needed for such refuse, but we use it also to express a place where the coal, wholly or partly, has been removed so that the roof has fallen or may be expected or desired shortly to fall. It does not include places where the coal has been extracted and in which it is desirable to keep rock from falling or being stowed. To express the place where the roof has fallen or may be expected to fall the English use "goaf" and where it has fallen the words "the broken." It would seem well to adopt "goaf" and to distinguish it from "gob," but there are other definitions that should be determined that are even more important than these. We only half know a science the definitions of which are contradictory and uncertain.

### Glamor from the Past

OUTSIDE the anthracite region how little has been written about the history of the coal industry! H. H. Stoek gave us a little about the Illinois field; something has been done, but meagerly, for Iowa; a little is vouchsafed about the Georges Creek field, Muhlenberg County in western Kentucky, the Hocking Valley and one or more other districts; but a complete history of American coal mining has yet to be written.

The anthracite region has been unusually fortunate. It contains some companies so old that they reach back to the early days. These companies have kept the story before the public, and, strange to say, those who would analyze the anthracite industry to its disadvantage usually have prefaced their remarks with a history of its development. In other sections no such close connection exists between the present and the past, and the work, if done, has been left to antiquarian societies.

Strange to say, no better way exists of reaching the public than through history. The public reveres its Lares and Penates, however questionable, and, truth to say, the original mine owners were respectable and respected. They were pioneers and builders. They were the "forty-niners" of the regions they developed. Around them can be weaved a romance; from them may be evolved a tradition.

Americans never speak ill of their forefathers. Enough of mystery surrounds the past that the names that survive are like the heroes of Greek mythology—supermen. Hence if we would have the public pay the industry the respect due to its importance and value, recall not so much our present-day leaders in mining as those that, being shrouded in antiquity, can be glossed with all the glories of the imagination. Back in past years were men whose ways were dubious. There are railroad men whose actions were questionable, more than questionable—in fine they were rascals—but the hand of time has dealt kindly with them. We

note now only their courage, their foresight, their energy and resourcefulness. The rest is quite generally forgiven, forgotten.

With these exemplars the coal industry does ill to pass over its pioneers. Through them, though they may not have been better than the general run of their enterprising neighbors in other industries, may be found a way to the hearts of the public. They are not less noble than those of our ancestors that burned what they chose to call "witches," that ducked the scolds and persecuted those who disagreed with them. Those who trace their origin from these originals regard that fact as a merit. Surely the story of the pioneers of our industry might be recited to give the public a sense that the mining of coal is "an ancient and honorable" industry, in the development of which the public might take a kindly and not an antagonistic interest.

Then also should we keep the history of the mechanical developments in coal mining. Just at present it is customary to speak of them with disrespect, but surely the story of mining is a record of achievement, no matter what is said. After all, in our transportation methods we are not so remiss. Cars go twice and thrice, even four or more times, to the working face every working day, under conditions of exceptional difficulty. The railroads would find it difficult to prove equal efficiency, even considering the greater distances to be traversed.

The past, of course, will not save the industry from censure. Our contemporaries are too wise to be hoodwinked, but with a goodly present and the glamor of the past we may attain the good word of the public despite the fact that no one is kindly disposed toward any essential industry. The credit of an historic past cannot save us from the consequences of our faults but may spare us unjustifiable persecution.

### Algebra First

HOW MANY first-class efforts to give helpful training of all kinds have been ruined by scholasticism. Many an attempt to give a man the results of experience has been sidetracked by the pedagogs who can see nothing but algebra, geometry and the relation between these studies and pneumatics, chemistry, hydraulics and what not. Industrial education has drifted so far in the wrong direction that the pupil has been discouraged or has been led finally to believe that according to his mathematical ability will his fitness for a position be judged.

In our mine foremen's examinations, unfortunately, we have put geometry, rather than safety, first. Our calculating fiends have put cube and square root where accident prevention should rightly be. The rigorous tests as to a knowledge of safe shooting, safe haulage and safety from gas have taken a back seat. "Let no one enter who is unacquainted with algebra" is our dictum instead of "Safety first." We need mathematical ability in engineers and a knowledge of plain figuring and simple mensuration in mine foremen, but so much geometry and so little safety in our examination questions for mine foremen has made these tests a farce. Looking at these questions would you believe that the mine foreman was about to undertake a responsibility in which men's very lives hung in the balance?

There are two kinds of coal miners today: Non-working union and non-union working.

# "The Hartshorns" Open Big Illinois Strip Pit

Careful Prospecting and Long Stripping Experience Utilized in Pit Layout—Except for One Shovel and Six Locomotives, Pit Will be Electrically Operated Throughout

BY E. W. DAVIDSON  
Assistant Editor, *Coal Age*  
Chicago, Ill.

**I**N THESE desperate days of high mining cost and abyssmal market the lure of the strip pit is strong among coal men. If they could but strike a piece of perfect strip land and steadily produce a lucrative stream of "dollar a ton" coal that would sell as fast as it was loaded out, what bliss life would hold for them! But it is axiomatic that strip property is often more heavily deposited with heartbreak than with coal.

As a result, successful coal stripping largely remains in the hands of men who have learned the science of stripping, and, although many new pits are opening up this year—three huge ones in Illinois alone—the most promising among them are operated by veterans who know that a strip mine, to be an earner, must contain the right kind of coal and plenty of it, that its operating conditions must be good and that its output must be clean, for the day of selling "any old thing" to the public is definitely passed.

Such a pit is the new mine operated by the Black Servant Coal Co., at Elkhart, Ill., on the western edge of the great southern Illinois field. The Black Servant Coal Co. really means "the Hartshorns of Danville," a family whose experience has contributed materially to the development of the stripping art in this country.

## STRIP PIT PROVIDED WITH FIVE-TRACK TIPPLE

The company has opened a 420-acre tract calculated to contain nearly five million tons of No. 6 blueband coal varying in thickness from 5 to 8 ft. under 20 to 45 ft. of cover. It also has an additional 600 acres under 45 to 70 ft. of cover with coal running up to 9 ft. in thickness. A five-track tipple has been built to prepare and load a maximum of 3,000 tons per day and production is now up to 2,000 tons a day. This plant bears many earmarks of an ideal stripping proposition. It has been working at least five days a week since last fall with few unbilled loads ever held over night—and this during a period when most of the deep mines of Illinois were either shut down or were getting two days a week of running time under a burden of "no bills."

Nobody knows better than the Hartshorns that there

is public prejudice against stripped coal. This prejudice has been created during past years when stripping was little more than a matter of ripping off some cover, running a string of railroad cars down into the pit and shoveling into them whatever coal was handy, along with any lumps of clay and shale that didn't get out of the way. Real preparation of strip coal—even washing in some regions—is more recent. But the prejudice still exists.

So the Black Servant Coal Co., following the trail that it and a handful of other big stripping concerns have blazed, set out at Elkhart to overcome a little of that prejudice by giving its output as careful a preparation as any strip pit product ever got, short of washing—a process considered unnecessary in this field.

Although there is a variation in the quality of the coal from section to section of the tract, due in part to the fact that a protecting stratum of limestone overlies only 60 to 70 acres of it, still, the whole coal bed is covered by 4 to 20 ft. of shale. As a result the sulphur impurities carried by ground

water have not raised the sulphur content of the coal to more than 3 per cent in any of the samples that have been tested. Analysis of four samples show heat values ranging from 11,500 to 12,233 B.t.u. per lb. The moisture content runs from 6.30 to 9.71 per cent, ash from 7.09 to 10.18 per cent and fixed carbon from 47.38 to 49.58 per cent. On such analyses as these, the coal is sold as a high-grade steam and good-quality domestic fuel.

More than twenty years ago the farmers of the region excavated a little of this coal for their own use at points near the outcrop of the measure. Geologic disturbances left the deposit so badly broken up, however, that there had never been any mining of consequence, in the bed nearer than the shaft mines at Dowell and Duquoin, two and eight miles respectively to the northeast, and at Hallidayboro, two miles to the southeast of Elkhart. The Hartshorns, with their Danville tracts exhausted, became interested in the region, however, and spent more than a year in prospecting it. Over 2,000 drill holes were sunk before 1,000 acres in two separate tracts were purchased in the winter and spring of 1922-1923.

Main Bottom at the Black Servant Strip Pit

Into this 50-ton hopper, feeding the hoist conveyor, ten-car trips from both sides of the mine deliver their loads. The track layout, when it is complete, will enable locomotives to dump their trips, three cars at a time, and proceed forward around a curve through a switch before they back their empties down into the works for reloading. Thus each side of the mine will have its own haulage operating unhampered by the other half of the mine.

**Few Strip Pits Have Such Tipples as This**

Five tracks, four of them provided with loading booms, together with efficient screening and picking arrangements, enable this tippie to furnish coal as carefully prepared as that coming from a shaft mine. Today the public is prejudiced against strip-pit coal. It is hoped that some of this aversion may be overcome by careful preparation.

In April, 1923, with the 420-acre tract thoroughly mapped, shovels started removing the cover. Tipple construction was begun at once. In November the first coal was loaded out, but without much preparation, for the tippie, designed and built by the Jeffrey Mfg. Co., was not put into operation until this spring. It was finally completed and accepted early in June. Only about two months more of development are required—granted a steady market—to get the stripping, loading and haulage systems lined up in their permanent form and the whole enterprise into full stride.

The tract to be stripped is, roughly, a mile and a quarter wide east and west, and half a mile deep north and south. A spur from the Illinois Central railroad skirts the northern edge of the pit as far as the tippie which stands a little east of center. The coal measure dips to this point and the loaded trips in the pit will have the advantage of an average 2 per cent grade, running down to a 50-ton dumping hopper. From that point a conveyor lifts the coal to the top of the tippie.

The working plan calls for stripping and loading on the advance through the property from north to south maintaining a cut in the form of a cross. Little or no coal will be lost. A thorough cut will be driven straight south from the main bottom, thus opening a permanent haulageway. A stripping and a loading shovel will work back and forth along each arm of the cross. The east and west workings thus are operated as independent units, each with its own haulage system. Three 20-ton steam locomotives are expected to operate in each unit. Each locomotive will handle nine or ten 6-ton cars per trip, moving the loads to the main center haulageway and thence northward to the dump hopper.

#### **CARS WILL BE DUMPED THREE AT A TIME**

The inner rail of each load track will be laid directly along the rim of the receiving hopper, into which the side-dump cars will discharge by threes. After dumping, the locomotive will push its trip of empties forward and around a curve laid close to the north bank of the pit. It then backs down the empty track past the dump hopper and onto the main line again for its run back to the loading shovel. Passing tracks at proper intervals will permit the steady operation of three such trips, for each half of the mine. The only double track will be that down the main center road so that there can be no interference between the two lines of haulage.

The two stripping shovels that are now in the mine will do most of the work of cover removal. They will be assisted, however, by a dragline with a 125-ft. boom

and a 3-yd. box. This machine will work ahead of the shovels on the thorough cuts, so as to move the spoil farther back than the big shovels can reach. One of the shovels is a 300-ton and the other a 350-ton machine. Each is fitted with an 8-yd. bucket and a 90-ft. boom. Of the two loaders mentioned earlier one is steam-operated and the other driven electrically. Both are mounted on caterpillar trucks. Each is equipped with a 2-yd. dipper and ordinarily loads two tons at a dip.

These machines load strips of coal 20 to 25 ft. wide, and the stripping shovels work behind them on berms at least 40 ft. wide, moving the spoil over into the place from which the coal has been removed. It is the effort, however, always to leave an open space in front of the coal face, so as to enable the loading shovel to remove coal with as little clay and other foreign matter mixed with it as possible.

The overburden is of such nature that the only cleaning of the coal bed necessary is done by two men with shovels and wire brooms. These men also lay track for the stripping machines. In parts of the mine already opened, the top of the coal is practically flat containing few pockets and dips such as require cleaning by hand. Throughout most of the work thus far performed, the track for the big shovels has been laid directly on the coal. Only occasionally has it been necessary to timber under the tracks. This simplifies track work to such a degree that two men comprise the entire track-laying crew for each stripper.

#### **SHOOTING RAILS FORWARD UNDER SHOVEL**

One further detail helps to simplify the work of the tracklayers. This is the use of two sections of roller conveyor as long as the shovel frame and suspended under the machines close to the ground. On these the short, heavy sections of rail at the rear of the shovel can be shot to the front whenever the shovel is ready to travel. This saves the time and labor necessary to carry the rails around by hand.

In parts of the pit the work of the stripping shovels is heavy not only because the cover in places runs as deep as 70 ft., but because of the presence in certain localities of heavy lime rock above the coal. Shots are placed in this stratum of sufficient strength to break it up fairly well. Churn drills working on the top of the bank, back from the cut, also put down holes on 20-ft. centers. These are used to shoot up the shale which rests immediately on the coal.

Where the proportion of rock in the spoil is great, one difficulty encountered in this stripping is avoided, for this rock reduces the tendency of the spoil bank to slide. The soil of the overburden is extremely slippery when wet. Because of this fact, throughout the early work in this pit, slides were frequent, covering up the coal face and causing trouble generally.

After several such occurrences the mine operators struck upon a way to put this slipperiness of the spoil to good use. If moisture would make the front of the spoil bank mobile, coasting dirt down into the cut, why would it not coast dirt down the other side as well? Accordingly a water line was run to the rear side of the bank on which each stripper was dumping spoil. A man was placed at this point with instructions to sluice down the rear slope so that each dipperful of dirt would skid to as distant a stopping place as possible. This expedient helped move back the weight of each waste bank and prevented the loss of much time and obviated

much plain and fancy "cussing" down in the workings proper.

Thus far, drainage in this strip pit has not been difficult. Lines of tile leading to the nearest pumping sump are laid under the advancing spoil banks. From the sumps the water is pumped out over the rim of the pit and discharged into convenient gulleys. Up to the present, nine comparatively small centrifugal pumps—one 8-in., four 4-in. and four 2-in.—have done all the work of draining the pit and have been used only periodically, thanks to the fact that the natural contour of the property drains both ways from a low divide running across the tract. A system of 4-ft. ditches encircling the entire pit also helps. Practically no surface water runs into the mine. Ground water and that which rains into the open workings is about all with which the pumps have to contend. The pit has never had to stop work on account of a flood—that bane of the average strip mine.

The mine is electrified throughout except for one of the small loading shovels and the haulage locomotives. Central-station power is delivered from a 33,000-volt line and is stepped down to 4,200 volts in the power company's substation on the property. Thence it goes to the coal company's combination switch house and electrical repair shop which contains the main oil circuit breaker and the metering equipment. One feeder line runs to a separate substation where the current for the tippie is stepped down to 440 volts and where oil-switch protection against overload helps to make the tippie power supply uninterrupted. An underground cable extends from the tippie substation to a central control "pulpit" from which all the motors in the building are started and stopped.

Other feeder lines run into the pit to serve the shovels, the pumps and the compressors that furnish air to the coal drills. Great care is exercised in taking this 4,200-volt power into the pit. Two miles of 3-phase line is built around the rim of the workings that are now active. Those lines that run along the north edge and the east and west ends of the property are carried on poles and the construction is permanent. The cross

line spanning the property on the south side of the workings will be moved southward from time to time to keep pace with the advancing face. It is always to be maintained at a considerable distance, at present 1,500 ft., back from the rim. Laterals tapping it at 1,000-ft. intervals extend northward toward the rim of the cut to supply the lines that actually run into the workings.

Two of these laterals are carried directly to the two big stripping shovels which require the full 4,200-volt current. Everything else in the pit operates on a potential of 440-volts. Portable substations, brought up close to the rim of the cut—but for safety's sake, not down into the pit—supply the loading shovels, the pumps and the compressors with 440-volt "juice." A safeguard against electrical accidents in the mine is provided through the use of a metallic neutral carried on all lines of consumption. By all these precautions in line building and protection the possibilities of accident are greatly reduced. Thus far no injury from electrical shock has been suffered by any employee.

#### COAL PRODUCED RECEIVES EXCELLENT PREPARATION

The five-track tippie is completely equipped to prepare and load mine run, 1½-in. screenings, 2 x 1½-in. nut, 3 x 2-in. nut, 3 x 6-in. egg, and 6-in. lump or any combination of these sizes. All grades above 1½-in. screenings can be delivered to a 400-ton-per-hour single-roll crusher. Of late much crushing has been done. The flexibility of the tippie equipment is noteworthy.

Coal is delivered from the big hopper on the main bottom of the pit to the tippie by means of a 48-in. steel-pan conveyor operated by a 100-hp. slip-ring motor taking 440 volts alternating current as do all the other motors in the tippie. The extra-long shaker screens have two cranks driven by a 40-hp. induction motor.

The over-all length of the shaker screens is 72 ft., and their width is 7 ft. There are 16 ft. of 1½-in., 14 ft. of 2-in., 12 ft. of 3-in. and 10 ft. of 6-in. perforations. In addition there are three more feet of 1½-in. perforations in a degradation screen set into the chute under

#### East Wing of Mine

At this particular point there is about 5 ft. of coal under 35 ft. of cover. Development has not yet progressed sufficiently to furnish the normal output. Eventually the two working faces will form practically a straight line extending across the property from east to west. Haulage will be along either face and thence down the main haulway northward to the tippie bottom. Note the limestone ledge which is over much of the coal and has to be blasted individually. It has aided in keeping the coal below it in good condition.

#### West Wing of Pit Is Only Well Started

This is a view looking west across the main bottom where a trip is being dumped three cars at a time. The haulage locomotives and one shovel are the only machine in the whole plant that are not operated electrically.

the 2-in. screen and a short 2-in. degradation screen under the 3-in. discharge, thus making separation of the small sizes as complete as possible.

The screenings fall directly from the shaker into a hopper delivering to railroad cars. By the use of a fly-gate all the screenings can be delivered to a conveyor extending along one wall of the tippie and parallel to the railroad tracks. This discharges to a flight conveyor running across the front of the tippie just above the forward ends of all the loading booms. This is the assembly or mixing conveyor.

The lower run of this mixing conveyor moves from the screenings side of the tippie to the lump side. Thus the screenings can be delivered alone by a drop gate and chute into any car on the five tracks or they can be mixed with any other size being loaded. Any of the other sizes can be cross-hauled by this mixing conveyor by the simple expedient of lifting the end of any loading boom so that it will deliver onto either the top or the lower run of the mixing conveyor, depending upon which direction the coal is to move. The upper run delivers to the crusher.

#### LARGER COAL SIZES ARE THOROUGHLY PICKED

Between the shaker screen and the loading booms are ample picking tables, each 26 ft. long. It is customary to employ 11 pickers. Four work on the lump table, four on egg, two on the 3 x 2-in. nut and one on the

2-in. nut. A refuse conveyor moves the pickings back toward the pit delivering them into a hopper from which trips can be loaded so that this material can be hauled back and dumped into areas from which the coal has been removed.

Railroad cars are moved by gravity from the point where they are delivered in the empty yard over a 2 per cent hump above the tippie until they have been lowered across an automatic recording scale into the flat-grade load-storage yard below. A caterpillar tractor has proved handy around the tippie for occasionally moving cars against the grade and forms the coal company's nearest approach to a switch engine. It was a highly useful piece of apparatus around the works during the early development stages. It moved everything that needed moving and did it with precision, neatness and dispatch.

The coal company has built a two-story brick office building and weigh house and a small bath house 150 yd. east of the tippie. Seldom are such substantial buildings seen around a strip pit.

The shop building is a 50 x 90-ft. steel structure and houses a most complete set of mine-shop equipment and a crew of mechanics. These latter under the direction of C. W. Norman, who is in charge of all top work, can do practically all the repairs that will ordinarily be necessary in the mine. They can do heavy forging on steel such as is used on the shovels, they can manufacture all the switches, frogs and steel ties the company uses. In fact they are balked at little or nothing.

The equipment of the shop consists of a forge, a 500-lb. power hammer, a 300-ton hydraulic press, a 24-in. shaper, 24-in. and 26-in. drill presses, 13-in. and 54-in. lathes, two emery-wheel stands, a 6 x 9-in. high-speed, power hack saw, oxycetylene welding and cutting torches, an electric welding outfit, a small power-driven air compressor and an assortment of small tools. Traveling cranes aid in handling heavy work. A pit has been sunk in the floor and eventually a track from the workings will be run directly into the shop to facilitate locomotive repairs.

The staff at this mine consists of W. B. Reid, general superintendent; Otto Ullom, field boss; F. S. Burns, electrical engineer; C. W. Norman, top boss; Henry Meyer, shovel boss, and E. H. Elder, chief engineer.

#### Black Servant Buildings Are Permanent

In the foreground is the main office and scale-house building while in the left background appears a portion of the wash house. Both have been built with the idea that they should last throughout the life of the property. Strip-mine buildings are seldom made as permanent as these.

#### Accident Rate at Coke Ovens Falls

Accidents in the coke-oven industry of the United States in the year 1923 killed 45 employees and injured 2,593, according to statistics compiled by the Bureau of Mines. Coke manufacturers employed during the year 23,729 men, a larger number than was employed either in 1921 or 1922. The accident rate for the industry was the lowest in 10 years, with the exception of the years 1915 and 1922. The reduction, however, was confined to accidents of a nonfatal character, as the fatality rate increased slightly as compared with the two preceding years. The accident rate for the year, based on 1,000 full-time, or 300-day workers, was 102.94, of which 1.76 represented the fatalities and 101.18 the nonfatal injuries. The fatality and injury rates for the year 1912 were 1.59 and 93.77, respectively, and those for the 5-year period 1916-1920 averaged 1.81 and 167.03. Comparing the rates for 1923 with those for the 5-year period, the fatality rate in 1923 represents a reduction of 3 per cent and the injury rate a reduction of 39 per cent.

# Recovery Work After the Castlegate Mine Disaster

## What It Taught and Exemplified\*

Typical Example of Organization and Recovery — Treatment of Bodies — Establishment of Ventilation — Testing of Apparatus Before Use — Inspection of Men on the Rescue Teams

BY A. L. MURRAY  
Surgeon, Bureau of Mines, Pittsburgh, Pa.

**R**ECOVERY of the Castlegate No. 2 mine at Castlegate, Utah, following the explosion of March 8, forms an excellent example of the organization that must be perfected and the procedure that is usually followed in the recovery of any large mine after a major disaster. Although each such occurrence has its own peculiarities, in which respect the one at Castlegate was no exception, yet the operations conducted after that explosion were of the type followed in recovery work in general.

The explosion in this mine occurred shortly after 8 o'clock on the morning of the date above mentioned. The day force had been underground only a short time, and the small night force had not yet left the operations. Every man underground at the time of the explosion—there were 171 in all—was killed.

On the morning of the disaster, the Utah Fuel Co., which had temporarily closed down its No. 1 operation replaced a number of the single men previously employed in No. 2 mine with older employees and married men from No. 1. This accounted in large measure for the large number of married men who lost their lives.

Immediately following the explosion, a call for rescue crews was sent out from the mine office to all coal-mining operations in the district. Within two hours teams from nearby camps were on the scene fitted with oxygen apparatus and ready to enter the mine. By afternoon more men were present than could be utilized at that stage in the recovery work. In all twenty-one apparatus teams took part in the work of exploration and recovery. They embraced six teams with the Paul and fifteen teams equipped with the Gibbs type apparatus. Both types gave excellent satisfaction.

The fact that twenty-one mine-rescue crews, all composed of trained men and provided with apparatus more than sufficient to equip them, could be assembled in less than twenty-four hours is a credit to the coal-mining companies of Carbon and Emery Counties, Utah. It also forms concrete evidence of the value and effectiveness of the training given apparatus crews by the Bureau of Mines. As these rescue teams reported for work they were grouped into three shifts, each consisting of seven apparatus crews.

Inasmuch as the change house adjacent to the main

mine portal was large, steam-heated and had an adequate supply of both hot and cold water it was selected as the apparatus base. Here all machines were cared for, recharged with oxygen, supplied with fresh regenerators and given a thorough test before being put to use underground. Suitable work benches were installed at one end of the change house, and experienced men assigned to the work of testing and recharging the

apparatus. An adequate supply of spare parts furnished from the surplus of the various companies which had teams present was kept on hand at all times.

From a preliminary survey of the conditions existing after the explosion, it was ascertained that roof falls and debris blocked the main portal of the mine. Accordingly, it was decided that an escapeway located about a quarter of a mile

up the canyon offered the best means of ingress and egress for exploration and recovery work. This opening was comparatively free from obstructions.

The general working schedule for the apparatus teams on each of the three 8-hr. shifts was as follows: Two teams were actively engaged in exploration and recovery work underground for a period of two hours, the actual time under oxygen varying from one hour to the full period. Two teams were held in support at the entrance of the escapeway ready to relieve the men underground at the end of their turn and also prepared to respond in case of emergency. The teams in support were housed in heated tents. The remaining three teams held in reserve rested at the change house.

### MOVE UP PAIRS OF TEAMS EVERY TWO HOURS

As the active teams completed their tour of duty underground, they returned to the change house to rest. Those in support took their place in the mine and two teams that had been resting at the change house moved up in support. Thus one team, the seventh on the shift, was available for any special exploration work or for replacements or as supernumeraries in case any member of the other teams became incapacitated. All teams, together with their apparatus, were transported from the change house to the escapeway and back by auto buses.

Each crew of apparatus men was supported by fresh-air crews—men who did not wear apparatus and worked only in sections of the mine where ventilation had been re-established. These men transported materials and

\*Published by permission of the Director, Bureau of Mines, Department of the Interior.

supplies to the apparatus crews, and received the bodies brought out by the rescue teams and carried them to the surface.

Each shift was under the direction and supervision of three experienced men selected from the mine superintendents, engineers and mine foremen of the various mines in the district. One of these supervisors directed the work at the apparatus base, one that at the mouth of the escapeway and one the operations underground. Although this distribution of the work formed the general plan of direction, in many instances the underground supervision was augmented by advisory members made up of the general manager, general superintendent and chief engineer of the Utah Fuel Co., the general superintendent and chief engineer of the United States Fuel Co., the chief mine inspector and the coal-mine inspector of Utah, and mining engineers from the federal Bureau of Mines.

As soon as possible after the explosion, the ventilating fan was placed in operation exhausting. This machine had not been damaged but the controlling doors for reversal of the air current had been jammed by the force of the explosion coming out of the aircourse. A general plan for exploring and recovering the mine through the escapeway which connected with the main slope by the second left dip entry almost midway of the operation was adopted.

By this means, fresh air entering the escapeway could be carried forward by temporary stoppings. The apparatus crews kept in advance of the fresh air making explorations and constructing new stoppings to which points the fresh air was successively carried. In this way, the recovery work was advanced in safe stages, down the dips on the left, back up the dips on the right and then on up the raises until the entire mine had been reclaimed.

On several occasions progress was appreciably delayed by fires. These had to be dealt with when met and had to be completely extinguished before further progress could be made. As soon as any section of the mine was cleared of gas, by having fresh air turned into it, a patrol of two men was established whose duty it was during their shift constantly to traverse the section watching for evidence of fires and testing the air for explosive mixtures of gas. Each of these men carried a safety lamp and a canary. These birds, which form one of the most reliable means of testing for carbon monoxide, were extensively used in this work. Although about seventy were available, fifty having been shipped to the mine the day following the explosion, only about forty were actually used. Of the forty birds, the lives of about sixteen were sacrificed in order that the men might be amply protected.

One lesson learned from the use of canaries at Castlegate is that carrying cages should be provided with wooden bottoms. Several all-metal cages with bottoms unprotected were in use. In every instance the birds occupying these cages developed an affection of the legs resembling rheumatism. This probably resulted from the chilling of their feet when the cages were exposed

to continuous currents of cold intake air. Birds so affected would not use the perch, but would squat on the bottom of the cage. Birds in wooden cages were not affected in this manner.

Again, at least one side, or better two adjacent sides, of the cage should be closed to protect the birds. Canaries are highly sensitive to drafts, and cages with two solid sides will permit exposure of the birds to mine atmospheres yet afford some protection from currents of cold air. At the Castlegate disaster there were more than enough birds for all testing purposes, but in cases of a similar nature elsewhere the number available might be limited and the needless disability of only a few birds might seriously handicap exploration and recovery work and possibly endanger the lives of men entombed.

During the early stages of the recovery work, hope was entertained that some of the miners might be found alive. As work progressed, however, and evidence of the extent and severity of the explosive blasts accumulated, the chances of finding anybody or anything alive in the mine became fainter and fainter. Nevertheless, hope and effort were ever spurred by such a possibility.

Whenever the rescue teams in exploration work discovered a body, it was

placed on a stretcher and carried to the nearest fresh-air base. Here it was turned over to a fresh-air crew and brought to the surface. Many such bodies had to be carried more than three-quarters of a mile. The first body of the 171 men who lost their lives in this disaster was taken from the mine about 11:45 p.m. on the day of the disaster, and the last of the bodies were brought out on Thursday, March 18, at 4 p.m. Work of recovering bodies was pushed as rapidly as was consistent with safety. But, as previously mentioned, fires greatly delayed operations. These had to be controlled and extinguished before further progress could be attempted.

Medical organization under the direction of Dr. McDermit, the camp surgeon, consisted of one physician at the morgue, one at the local hospital, two on 12-hr. shifts at the apparatus base and six on 8-hr. shifts at the escapeway opening. The duties of these men were as follows: The physician at the morgue was Dr. McDermit, who was acquainted with most of the men at the mine as well as with their families. He completed identification of bodies where doubt existed, saw to the issuance of death certificates and burial or shipping permits.

The physician at the hospital cared for patients sent there and looked after the general medical welfare of the camp. Those stationed at the apparatus base examined members of the various teams before they went on shift, supervised the disinfection of apparatus mouthpieces and their covering with sterile gauze while awaiting use, the disinfection of hands of members of teams as they came off shift and the caring for and dressing of cuts, bruises and abrasions so as to prevent possibility of infections.

The reason for exercising so much care on the disin-

### DANGERS OF DOING ONE'S UTMOST

**I**N the recovery work, strain completely unnerved one apparatus man, and when his nose clip was brushed off he fought with his team mates and was brought to the surface still struggling. Unfortunately the captain's nose clip was dislodged in the struggle. When found he was already dead. It is believed his fatigue prevented him from making necessary adjustments. Later the work was better organized and none was allowed to do more than he could safely perform.

fection and protection of apparatus mouthpieces will be realized when the large number of men using apparatus is considered and when it is remembered that the same apparatus was not worn by the same man on the various shifts. Careful disinfection of the hands of the team members as they came of shift, as well as the protection by proper dressing of bruises, abrasions and cuts was necessary in order to protect the men from the results of a possible infection incurred while handling bodies in the mine.

#### IDENTIFICATION OF BODIES EXTREMELY CAREFUL

The physicians stationed at the escapeway received and examined all bodies removed from the mine with a view to aiding in their identification through mine checks, clothing, articles found in the clothing or peculiar body marks. For each body removed careful notes were made as to place of recovery and anything found about or on the body that could in any way aid in identification. These doctors were equipped also with necessary materials to care for any injury received by the men when in the mine. The physicians who assisted in the work at this disaster, aside from two from the Utah Fuel Co., were mainly those from surrounding towns and coal operations, as well as myself.

The Knights of Pythias Hall at Castlegate was turned over for use as a morgue and corps of sixteen undertakers was on duty constantly. In addition to these, the various Carbon County Posts of the American Legion kept a large number of men at the morgue to assist in handling the bodies and preparing them for burial. As rapidly as bodies were positively identified, prepared for interment and placed in caskets, they were removed to the Community Hall nearby.

#### ANIMAL CARCASSES TREATED WITH CHEMICALS

In addition to the 171 men, nineteen horses and mules were killed underground. No attempt was made to remove the putrid carcasses of these animals. Whenever one was discovered, chloride of lime was sprinkled over it and later, men in apparatus chopped open the abdominal and chest cavities, placing quick lime therein as well as over the entire carcass. By the action of this material through the absorption of body fluids, such carcasses were reduced eventually to dry flesh, skin and bone which could be removed later with little difficulty.

For the comfort of the men engaged in recovery work, the company maintained two canteens where hot coffee, sandwiches, fruit and tobacco were kept on hand at all times for free distribution. One of these canteens was placed near the apparatus base in the change house and the other near the escapeway. In addition to these comforts, the company also supplied both rescue crews and fresh-air men with the necessary changes of overalls, jumpers, socks, underwear, shoes and cotton gloves. During the later stages of the recovery work, electrician's rubber-faced gloves of a heavy type were furnished the crews which handled bodies.

From all the evidence obtainable, it is believed that death was instantaneous in every case. This was evident from the positions and attitudes in which the bodies were found, not a man having moved from the place occupied at the time of the first blast except, of course, those thrown an appreciable distance by the violence of the explosion. Not a single instance could be found where it was indicated that a man had

struggled or made any attempt to protect or save himself. A careful examination of the bodies showed carbon-monoxide saturation of the blood which, except for the few men who undoubtedly were killed instantly by direct violence from the initial blast, was the accepted cause of death.

Examination of the mine showed that the violence of the explosion varied in different sections, in some places being extreme and in others comparatively slight. Regardless of the violence shown in any given section, however, it is believed by those who made a careful examination that the initial explosions were of sufficient intensity to deplete most of the mine air of its oxygen and that the carbon-monoxide content of the afterdamp which quickly spread to every part of the mine except possibly the face workings at the top of the raises, was so high that no living thing could have survived it more than 30 sec. The thick bed of coal worked in this operation, the straight continuous main slope extending throughout the entire length of the mine and the numerous crosscuts no doubt appreciably aided in flooding the mine with afterdamp.

#### EVERYBODY BURNED BUT SOME AFTER DEATH

Burns were evident on everybody removed from the mine. Naturally, these were most severe on the exposed parts, such as the hands and faces, and in most instances these presented a complete charring of the surfaces, into which had been driven fine pieces of coked coal. On those bodies where the clothing had not been torn or burned away (the majority were found fully clothed), areas giving every evidence of burns from dry heat were found. All this burning apparently occurred after death, as no evidence was discovered of blistering or an inflammatory area surrounding the burns. This further strengthens the supposition that death in practically every case was due to carbon-monoxide poisoning. Severe burning of the face of nearly every one of the bodies necessitated care in noting the places where the bodies were found, and rendered it important to make a careful search of the clothing as well as an examination for peculiar body marks for purposes of identification.

#### COKED COAL DRIVEN INTO BURNED SURFACES

Small pieces of coked coal driven into the burned surfaces gives fair evidence that most of the burns were caused after death by the final dust explosion which was characterized by longer and more intense flame and by the formation of coke dust.

The apparatus crews worked a total of 121 shifts, or an average of 6 shifts each. Total rescue-apparatus hours amounted to 3,840 and only one serious accident was recorded during the time that work was in progress.

During the afternoon of the day on which the explosion occurred several men working in the open air on a fall of rock at the portal of the main opening, at least 20 ft. from the mine mouth, were overcome by gases issuing from the workings. At least eight hours had elapsed since the last explosion and much fresh air had been entering the mine meanwhile through the escapeway, yet the monoxide content of the mine air was sufficient to cause these men 20 ft. outside of the workings to be overcome. All of these men made a quick recovery when removed beyond reach of the fumes and given a short period of oxygen inhalation.

One highly unfortunate accident was the death of

a member of one of the rescue crews. During the first afternoon one of the teams from Spring Canyon, which had already made four exploratory trips into the mine, was on its fifth trip about 1,300 ft. in at a point where the going was difficult. One of the crew in passing another brushed off his nose clip. The man whose nose clip was thus removed became panicky, requiring considerable effort on the part of the balance of the crew to control him. With his nose clip replaced, he was being brought to the surface still struggling and wrestling. In attempting to keep the man quiet the captain had his own nose clip knocked off and possibly his mouthpiece dislodged.

At this time the team was still several hundred feet from the mine opening. The captain stopped, evidently to replace his nose clip, while the remaining members of the team continued with their partially overcome team mate to the surface. As soon as they reached the outside, Captain Wilson's absence was noted and a new team entered the mine and brought him out. Arrived at the surface, however, no signs of life could be detected, but artificial respiration and oxygen inhalations were administered and kept up continuously for more than an hour. Adrenalin injections were also given, but the heart and respiration failed to respond to anything that medical science could offer for resuscitation. This man left a wife and two small children.

#### FATIGUE PROBABLY CONTRIBUTED TO DEATH

Captain Wilson's unfortunate death occurred during the early hours of recovery work before complete organization of forces was possible. It is believed that a contributory cause to this accident was fatigue. The first teams on the scene naturally desired to accomplish the utmost possible toward the rescue of those in the mine, especially as hopes were entertained that many still might be alive. The repeated trips made by this crew undoubtedly caused fatigue which in the stress of their enthusiasm and excitement was little noticed. When a crucial moment arrived when reserve strength was necessary, a fatigued body could not endure the strain. This was evidenced both by the lack of nervous stability on the part of the man whose nose clip was first knocked off and again by Captain Wilson when his strength was not sufficient for him to right his apparatus and make his way 300 ft. to fresh air.

Later on when organization of the work and forces had been accomplished every rescue team before entering the mine was given a careful examination by a physician and upon the least sign of fatigue or other incapacitating condition, the men were forbidden to wear apparatus. After the establishment of this inspection, not a single accident occurred. On several occasions, however, men were excluded from teams for causes which in the opinion of the examining physicians made their use of apparatus not only a possible source of danger to themselves, but also to their team mates.

**LIQUID OXYGEN NOT SUITED TO COAL MINES**—Studies made by the Bureau of Mines indicate that though liquid-oxygen explosives may be used to advantage, especially in the lessening of blasting costs in iron, salt and other mineral mines and quarries, preliminary tests indicate that they are not suitable for use in gaseous and dusty coal mines. Experiments, however, offer some hope of so modifying these explosives that they may be made suitable for certain uses in such mines.

## Deadly Air Blasts from Falling Roof Rock Kill Many Miners in India

BY DAVID PENMAN

**M**OST of the workable seams in British India are of great thickness. This is particularly true of the mines of Bengal, Bihar and Orissa, where over 90 per cent of the total coal output of India is produced. Seams of 20 and 30 ft. in thickness are common, and in some cases coals 90 ft. thick, and even more, are found. In one instance 150 ft. of coal in one continuous seam has been reported.

Air-blasts, due to the sudden expulsion of air from the collapse of a large area, are not uncommon in Indian mines. One such occurred in 1923 in a mine of the Central Provinces. The area which collapsed was not unusually large, about 5,000 sq.ft. perhaps, and the seam was only 3 ft. thick; but the air in that space was propelled with such force through a narrow surface incline that fourteen persons who happened to be sitting in the incline entrance, preparatory to entering the mine, were hurled through the air for distances varying up to as much as 200 ft. Of these fourteen, twelve were killed outright and one died from the injuries received. In another instance five persons who had retired from a mined-out area on which the roof was weighting to what they thought was a safe position were blown off their feet and dashed against the sides and floor of the gallery. They were all injured, but fortunately none died.

As already has been mentioned, the roof is as a rule strong, and in consequence large areas are often mined out before the main roof gives way. Sometimes the goaf may be standing like a colossal hall, perhaps 400 ft. square, and not a sign of a break be apparent. A collapse of such a size in a 20-ft. seam would displace a volume of air of over 3,000,000 cu.ft. Assuming the actual collapse to occupy an interval of one minute, the velocity of exit of the air through a pair of shafts 18 ft. in diameter would approximate to a mile a minute. Sometimes the actual "fall" occupies much less than a minute.

If the whole area collapsed simultaneously from the surface (which is what probably happened in the mine of the Central Provinces just mentioned above), according to the law of falling bodies the fall in a 20-ft. seam would occupy only slightly more than one second. The collapse of a large area, however, is generally made up of a series of falls, and moreover some of the displaced air finds room in the spaces between the blocks of stone or in upper cavities left by the falls, so that the actual expulsion of air is always less both in volume and in velocity than the theoretical figures based on the assumption that the whole mass fell simultaneously and freely. Nevertheless, the danger is one that must be kept in mind by those who have charge of mines in which large areas of uncollapsed goaf occur.

It has been suggested that the sudden compression of the air at the instant of the discharge of explosives may result in a temperature sufficiently high to ignite an inflammable mixture of firedamp and air. The sudden compression of the mine air due to a large fall of roof must similarly bring about a considerable increase of temperature.

NOTE—From a paper entitled "Some Problems of Indian Coal Mining" read before The Mining Institute of Scotland at its Dunfermline meeting.

# Narrowing the Gulf Between Banker and Promoter

What the Banker Will Want to Have in Black and White —  
He Doesn't Know the Coal Industry but He Does Know Finance  
and He Will Ask Questions You May Not Have Duly Considered

BY P. H. GROSSMAN

Natural Resource Division, The American Appraisal Co.,  
Milwaukee, Wis.

IT IS sometimes said, by promoters, that bankers are the despair of those who would develop the natural resources of this country. It is also as frequently said, by bankers, that promoters are the despair of those who would soundly exploit our great natural resources. It is, in other words, quite evident to the student of the situation that a broad and sometimes impassable gulf separates the two.

The difficulty, like so many of its kind, seems to lie in a more or less superficial misunderstanding rather than in any deep-seated differences of viewpoint. The solution would seem to be a clearer understanding by each of the position of the other and of the means for bringing both banker and promoter together on a common ground.

To say that all bankers classify all natural resource developments as extremely hazardous is as erroneous as to endow all promoters with a belief that all their undertakings are absolutely safe and sound. The banker is primarily a conservator of wealth. The implicit trust imposed in him by the depositors of his bank, forces him to take a negative attitude until the merits of a proposition have been definitely proved to him. He is a banker first and last, and not a promoter. The banker's attitude toward a promoter must be based entirely on the evidence submitted to him: The examination of the property, a prospectus outlining the alleged development possibilities with a statement of expected earnings, prepared, all too briefly, by the promoters; and in most cases a rather glibly optimistic presentation.

Instantly, there arises in the banker's mind that basic element of banking, the seriousness of which only a banker can fully comprehend: "Suppose you fail, what will the investors get for the money I told them to give you?" The banker can be favorable only when every reasonable doubt has been banished from his mind.

For this incredulous attitude, the promoter is most to blame. A resumé of natural-resource financing for the past ten years or more would reveal an unfortunately large number of instances in which bankers, and through them investors, succumbed to the unlightened, if not frankly misrepresented, optimism of the promoters. The promoter never concedes that failure in his particular enterprise is possible. As a class, therefore, he is regarded as radical, as a dreamer, one to whom the unproven is real, one with unbounded enthusiasm, one whose sound business judgment is warped by his ambition, one who enters into a project

body and soul with little or no knowledge of the infinite details involved in the recovery of natural resources. It is this type of promoter who is directly responsible for the failure of many laudable enterprises to bear fruit, and for the abandonment of many properties which with proper financing and administration should have been profitable enterprises.

The question immediately arises as to how we can overcome this divergence of viewpoint. Our industrial and economic future which is dependent upon the development of our great wealth of natural resources, requires the sincerest co-operation between promotion and finance with unison of effort and understanding toward a common end.

Surely we cannot continue forever to attempt to

hurdle the wide gap between proposed enterprise and the source of finance, only to fall midway down the chasm which is becoming deeper and more difficult of spanning, because of the visionary attitude of the promoter on the one side and the unconsciously retrogressive attitude of the banker on the other.

What is the remedy of this situation, for remedy there must be? There can be only one answer: First, the use and dependence upon facts rather than dreams on the part of both banker and promoter; and second, the discovery and presentation of all relevant facts in each instance. This means, simply, that before he approaches a banker, the promoter should arm himself with all provable and reasonable facts regarding the raw material in the ground, the process of its extraction, the manufacture or fabrication, its distribution, and finally its potential usage. Only with such compendiums of facts, but with assurance if they are presented, can promotion and finance arrive at a mutual understanding.

The marshalling of this evidence is not a task for either the banker or the promoter. In the first place, both are interested parties, and both must consequently though unconsciously see things through the eyes of preference or prejudice. Neither has the facilities, the training, the experience, or the time to make a sufficiently adequate investigation. Both, however, can avail themselves of the services of organizations with a personnel of specialized training, each individual of which has the intellect and power to rid himself of any preconceived conclusions and to start out with a desire for the truth with facts as his only objective.

The facts are there. It is the natural-resource appraiser's duty to find them. He can add nothing to

---

THE banker must leave the appraisal of the property and the question as to the marketability of the product in the hands of technical men in whom he has confidence and on whom he must rely sometimes not only for the mere facts, but also for the main inferences to be drawn from those facts, for being a novice at the industry he is without power of comparison.

---

nature. He can only bring a trained mind to bear upon the gleaning of these facts. His investigations are unimpassioned but relentless. His findings are disinterested and authoritative.

The appraiser of natural resources must be more than an engineer. He must have the acute perception of the engineer, but he must combine with this the viewpoint of the investor, of the banker, and of the promoter. He must see details as they affect the whole. He must have the ability, the courage, and the conviction to conduct his investigations in an unbiased manner, with consideration of all hazards as well as of all advantages incident to the particular case. He must be competent to withstand the ambitious optimism of the promoter as well as the conservative pessimism of the banker. He must, in other words, arrive at his conclusions and present them in such manner as to be of the greatest possible assistance in the exploitation of our natural resources.

Much might be said about the qualifications of the natural-resource appraiser, and much should be understood by the banker and the promoter who are to successfully employ his services. The appraiser must be competent to test his own conclusions in the practical affairs of life, and if he has not the time or opportunity to do this, he must be eager to have other competent persons do it for him. He must be a guide in, and inspiration to, industrial progress. And above all he must be the rectifier of errors. There are few individuals or organizations so constructed as to be better or more exclusively devoted to the public good.

#### PROMOTERS FAIL TO SEE GLARING HAZARDS

The need for his services is peculiarly manifest in the promotion of undeveloped or only partially developed properties which have no history of operation. All too frequently in these instances, glaring hazards are overlooked or powerful advantages missed because of a too cursory view of the process. The following case is typical: Certain promoters desired to finance the acquisition of a certain marble deposit. The property consisted of several hundred acres of land underlaid with the deposit and equipment worth about \$100,000.

The product of the deposit was of unusual quality, and in a quantity that could not be exhausted in less than 300 to 400 years. These two elements were so plainly evident that the promoters, in their overabundance of enthusiasm, failed to give proper consideration to the great number of other facts which in this instance were of even greater importance, nor did they believe that anything else mattered once the facts as to quality and quantity had been definitely established. They failed to ask themselves and then answer the question "What will we do with it after we have it?"

They had a definite financial program in mind, which, however, was not acceptable to the financial interests approached, and was entirely changed after an investigation and analysis by an appraisal organization of the following points to which the promoters did not attach sufficient importance:

LOCATION:	Size, area underlaid, remoteness from metropolitan influence and nearness to other operations of a similar character.
EXPLORATION:	Method used, when, by whom, to what depth, and at what points on the property.
QUALITY:	Chemical and mechanical analysis and uses to which the product could be adapted.
RECOVERY:	Relation of quantity of commercially recoverable quantity to the total quantity in place.
DEVELOPMENT:	Cost of equipment, and all operations necessary to open the deposit to a point of commercially profitable recovery, representing capital invested.
COST OF RECOVERY:	Administration, labor, power, supplies, compensation and other insurance, taxes, depreciation and maintenance on equipment necessary for and devoted to recovery, working capital, interest on investment, and contingencies.
WASTE:	Relation of quantity quarried or mined to quantity commercially salable.
SHIPPING FACILITIES:	Nearness to and extent of railroad and water connections.
MARKET:	Where, to whom, in what quantity, for what purpose, at what freight rates, at what selling prices, from what source is this market now supplied? What quantity and quality of product is being supplied by competing operations?

Through analysis of these elements and the facts affecting them the reasonable expected gross return from which the cost of recovery is subtracted results in the net earnings available.

The net earnings in this instance were far from sufficient to justify the capitalization as proposed by the promoters, and thoroughly illustrated the folly of their financial program. Through the analysis that was made, however, elements of extreme importance were revealed to the promoters, thereby permitting intelligent construction of their organization and providing for certain advantages of which they knew nothing.

Only an organization thoroughly equipped beyond its engineering talent with ample reference resource, authentic statistical data, and an appraisal personnel of practical judgment, gained through years of experience, can in these unproven cases fairly and open-mindedly consider the hazards as well as the advantages in a manner which is of inestimable value to the proposed operators, of real assistance to the bankers, and of protection to the investor. Such an organization creates a situation built upon facts and affords an opportunity for sane discussion on a mutually understood basis.

#### APPRAISAL ORGANIZATION AIDS ALL PROPERTY

Even in the case of developed properties having a history of operation there is need for such services. These properties are too frequently found warped by weight of their own internal affairs; their management is often totally oblivious to progress in their own field of endeavor. An appraisal organization composed of specialists offers the best antidote for such and other business diseases. The appraisal investigation and analysis often provides for a new program of progress, many times bringing tottering businesses to their senses and frequently proving to the outside world that a particular enterprise has real merit and can proceed successfully with the aid of finance which it can get only through the uncovering of facts properly analyzed and presented in an understandable manner to the wants of those who "must be shown" in order to become convinced that the particular business is deserving of the financial assistance desired.

In cases where new projects are proposed as in the case of undeveloped properties, or, in cases where additional capital is required, the appraiser renders the most important service. He must be competent to determine the soundness of the new investments, the dependability of income to the investor, and to what degree the principal invested will be safeguarded, the adequacy of the security, and the degree of certainty of the borrower to pay the stated interest.

In one case, for instance, an operator needed added capital to the extent of a half a million dollars, but had difficulty in obtaining it. He knew his own business thoroughly, but he alone knew it. In approaching financial interests he was unable to present his problem in a manner free from conscious or unconscious bias. The statement of earnings as presented by him showed a rather substantial net income, but after the same process of investigation and analysis as was described above, it was revealed that the earning statement compiled by him was wrong.

He had charged to operating expense items properly belonging to capital account, and it was further revealed that a byproduct which had been given little attention in the past, could be diverted to a market which would bring a rather substantial return. As a result an earn-

ing statement was compiled which when presented with a detailed appraisal of the plant and its equipment showed the desired loan of half a million dollars more than justified and it was quickly obtained.

The value of any natural resource is dependent upon its earning ability and it is, therefore, fundamental that proper recognition be given to all relevant facts affecting the recovery, processing, marketing and utilization of the product and their collective influence upon the expected earning capacity of the enterprise.

Only after all investigation and necessary analytical work to determine the extent and truth of the advantages and hazards affecting these elements has been properly completed, can the facts be revealed and assembled into a workable plan of operation. A statement of anticipated earnings can then be compiled to show an expected net income which when capitalized in accordance with standard practices will result in the present fair value of the deposit.

Properties of real merit have failed to get started and may have failed in their infancy because of an improper beginning. In each instance it would probably be found that the underlying cause of these failures was the lack of a competent appraisal analysis compiled in a businesslike manner.

## The Miner's Torch

### Who Envies the Engineer?

IN THE course of a business transaction in which I have just been concerned I fell heir to a report covering the trusteeship of a coal-mining property dated only a few years back, and because it happened that at the moment when I first saw the report I had a few idle moments on my hands I read the report through carefully, which is something that I or no other person could have done ordinarily.

We hear much about the fees earned by professional men in the so-called learned professions in contrast to the fees earned by engineers. The report that I have just mentioned contained some sure enough first hand reliable information along that line and I am loaded now for the next college professor who tries to tell me that all this talk about engineers being poorly paid is untrue and harmful to the profession.

Boiled down the events contained in the "account" ran something like this:

(Act 1). Company thrown into bankruptcy with no money in sight to pay any of its creditors and all of its stock (\$200,000 original value) declared worthless. \$200,000 in bonds probably fully secured as the land and improvements were always considered worth in excess of \$300,000.

(Act 2.) Trustee in Bankruptcy appointed followed six months later by a Bondholders Protective Committee. All operations had been discontinued before the Trustee was appointed.

(Act 3). The lawyers appointed by the Protective Committee recommend a consulting engineer and he is employed to appraise the property and suggest, if possible, a purchaser to be interested in the property at the engineer's valuation.

(Act 4). Valuation report is submitted and purchaser located by the engineer who agrees to pay \$220,000 in cash and assume all outstanding bonds.

(Act 5). Committee makes final accounting and accounts for the \$220,000 in cash about as follows:

Compensation for fees and expense of counsel for Committee .....	\$50,000
Compensation of Committee .....	25,000
Compensation paid to Secretary of Committee .....	5,000
General expense including reports on property and all engineering services .....	11,000
Trustee in Bankruptcy .....	100,000
Taxes and Insurance .....	12,000
	<hr/>
	\$203,000

Amount for distribution to depositors of bonds..... 20,000

I was tempted to underscore certain items but it occurred to me on second thought that they might be construed as "contempt of court."

WASHES DIRT OFF COAL WITH WATER.—At the strip pit of the Harrisburg Coal Mining Co., Harrisburg, Ill., the overburden, 45 ft. thick, is removed by a large steam shovel and then the surface of the coal is scraped free of impurities. That done, the top of the coal is generously flushed with water from large reservoirs nearby. In this way the coal is rendered clean of overburden, but before it is cleaned of those impurities which go with the bed it passes over the screen and in so doing is thoroughly sprayed to move any overburden or bottom clay that by chance may have mixed with the coal.

BROWN COALS may be developed in various parts of the empire as a useful fuel, according to W. A. Bone, Professor of Chemical Technology at the Imperial College of Science, who, in an address to the British Association for the Advancement of Science in session in Toronto, pointed out that these coals are found in extensive deposits in the various colonies and dominions. He suggested that research by chemists and engineers will make it possible to utilize many of these reserves which are at present receiving little attention.

# How a Copper-to-Steel Bond Is Made, with Tests Proving Its Efficiency and Endurance

Direct Union of the Copper Terminal to Rail Provides High Electrical Conductivity—Mold Confines Heat to Terminal While Bond Is Being Formed—Copper Sleeve Protects Strands of Cable Against Breakage

By J. B. AUSTIN

Research Engineer, The Rail Welding and Bonding Co.,  
Cleveland, Ohio

**M**UCH PROGRESS has been made in the welding of copper to steel, in the design of bonds and molds and in the method of applying the all-copper bond. This process of welding copper to steel is well adapted to the bonding of mine tracks.

Each step in the development has been the outcome of careful tests in which the relation of any part of the process to the general problem has always been considered. In consequence of the many investigations, a simple, quick and reliable process has been evolved, providing a permanent electrical connection between rails that is cheaply and easily installed. As the sole object of the bond is to bridge the gap between the rails it seems only logical that this path should be copper. Such a bond is made by directly welding the all-copper bond terminals to the rail with copper.

In welding the terminal of an all-copper bond to the rail, it was soon learned that a mold was necessary in order to hold the weld metal in proper position in relation to the bond head. Copper melted under the electric arc is quite fluid, and without the mold it is impossible to retain the metal in contact with the rail. With such a mold, the bond is held in its correct position, relative to the rail, and the weld is confined to its proper limits. The casting is also compact and uniform in size. The metal can be positioned properly by the mold, the welder can focus his entire attention on the actual welding operation much improving the quality of his work.

The process of arc-welding copper to steel requires that the molten copper shall not only be held in contact with the rail but shall also be hot enough to bring the surface of the rail to such a temperature as will eliminate rust and scale and effect the weld. In building up a weld, it was found that the lower layers of copper were likely to chill against the rail. A refractory mold eliminated this chilling to a large extent by retaining the heat within the mold. Many materials were tested, and carbon was selected as the most suitable mold material because of its comparatively high electrical conductivity and its low heat conductivity. It was the only material tested which satisfactorily withstood the intense heat of the arc without mechanical failure or rapid deterioration.

## OLD PROCESS OF WELDING COPPER TO STEEL

The original process of welding consisted of melting scrap copper into a carbon mold by means of a carbon arc. In order to obtain a satisfactory weld with pure copper, it was necessary to direct the arc directly into the rail and to wash the scale oxide free so that the surfaces of the metals where in contact were clean. A weld was then made, but when the copper of such a weld was sheared from the steel, much porosity was noticed along the welding surface.

Further examination with the microscope showed that a weld of this type was of a questionable character. Between the copper and steel there was a rather wide brittle alloy zone in which were many fine hair-line cracks. This zone was in some cases  $\frac{1}{8}$  in. to  $\frac{1}{4}$  in. wide. The conclusion drawn from these tests was that any nicking or gouging of the rail was distinctly detrimental to the rail, as well as to the bond-head casting.

## COPPER-SILICON ALLOY MAKES BEST WELDING ROD

Extensive investigations were then made to obtain a flux or alloy which would eliminate the gases from the molten copper and reduce the oxide scale without what had been the inevitable gouging of the rail. Many different elements were tested as alloys, and probably 600 or more welds were made before a suitable element in the proper proportion was obtained.

As a result of this investigation, an alloy copper rod was developed which thoroughly eliminated the gases from the copper and from the surfaces between the copper and the steel. This rod contains a powerful deoxidizer which has the special advantages of reducing the oxide scale at a relatively low temperature, and of giving a resulting casting of relatively high electrical conductivity. This fluxing action permits clean degasified surfaces of copper and steel to come into intimate contact so that a weld can be made over the entire contact area.

In order to weld this copper-silicon alloy to steel it is only necessary to melt the alloy adjacent to the steel and play the arc upon it for a brief time. The rail is not gouged at any time, for the arc is played directly upon the copper. In shearing the weld metal from the steel, there is not the abrupt failure which character-

ized the rather brittle weld of pure copper to steel. Instead, the copper weld metal, which was dense, non-porous, fine-grained and ductile, sheared slowly. Microscopic examination of this union showed a distinct line of contact between the copper and steel. The alloy zone which joined the copper and steel when observed under high-power magnification showed that it varied but little

Fig. 1—Microscopic Structure

Photomicrograph of a copper-to-steel weld made with the new copper-silicon electrode. Note the absence of porosity and the uniformity of the union between copper and steel.

**Fig. 2—Mold in Position for Making Weld**  
A 4/0 base bond and mold are shown ready for welding. The mold holds the copper cable in place and retains the deposited metal. The arc is first drawn from the carbon mold.

in width. The hair-line cracks observed in previous welds made by the gouging process were entirely absent. Fig. 1 is a photomicrograph of a copper to steel weld made by this new process.

Two processes have been developed for applying all-copper rail bonds. The results obtained with either process are identical. They are known as the carbon-arc and the copper-electrode process. The former involves the use of a dynamotor which reduces the open-circuit voltage to about 60 volts, suitable for carbon-arc welding and sets up a local welding circuit with the rail of positive polarity and the carbon electrode of negative.

The alloy rod is then melted by means of the carbon arc. In the latter process either a dynamotor or a resistance welder is used, and the arc is drawn between the copper electrode and the mold. In the carbon-arc process, the electrode and the filler rod are separate, whereas in the copper-electrode process, they are one and the same. As the latter process is that used in the mines the rest of this article will be confined to a detailed description of the process as it has been developed for the application of mine bonds.

**ALLOY CLEANS RAIL OF SCALE AND RUST**

The process of applying a base bond may be described as follows: Excessive scale and rust are removed with a file or wire brush where the weld is to be made. It is not necessary to grind the rail as the alloy rod cleans the rail during the welding process. A current of 200 amp. is best for welding a 4/0 base bond.

Fig. 2 shows the position of the bond and mold ready for welding. The mold fits snugly against the web of the rail. This photograph also illustrates the use of the mold as a positioner for the bond.

The first step in the process is shown by Fig. 3. The arc is drawn from the carbon mold and with an arc length of about  $\frac{1}{4}$  in. the metal is deposited as indicated by the arrow starting at the extreme right. During this step, the first layer of metal is deposited and the weld to the rail is obtained.

The second step in the process is shown by Fig. 4, the pool of the first layer of copper is now attached to the cable. This is accomplished by directing the arc at the head of the bond on its lower side, near the rail flange.

The third and final step of the process consists of advancing the arc over the entire area and melting down the bond head and washing the copper against

the web as the molten pool of copper rises in the mold. The arc length may be  $\frac{1}{4}$  in. to  $\frac{3}{4}$  in. and still the results will be satisfactory. Fig. 5 shows the completed weld. In welding a 4/0 bond head by this process about 40 sec. is required to complete the entire series of operations.

**RESISTANCE LOWERED WHEN ALLOY WAS USED**

Resistance measurements were made of a number of bonds welded with pure copper and the silicon-copper alloy rod by the bridge method. Tests of the same bonds were made by the volt-ammeter method. The voltage drop was measured across the bond head on the center of the rail head with a current of about 275 amp. through the bond. Though this test is not as accurate as the bridge method the error is about the same for each type of rod and the results shown in Table I therefore are comparable.

Table I—Resistance of Pure-Copper and Silicon-Copper Bonds			
Type of Rod	Number of Bonds Tested	Average Equipment Feet of 6-In. 100-lb. Rail	Volt-Ammeter Resistance of Bond in Ohms
Pure Copper.....	4	3.146	0.0000305
Silicon-Copper.....	4	3.042	0.0000294

The test shows that because of the elimination of porosity the use of the silicon-copper alloy slightly lowers the resistance. A small percentage of silicon remains in the finished bond head. The larger percentage of silicon in the original rod is used up in the reduction of the oxide. It is also interesting to note that of many of the alloys that might be used for welding copper to steel, the silicon-copper alloy lowers the electrical conductivity the least.

Comparative shear tests were made of pure-copper-to-steel welds and silicon-copper-to-steel welds. The bonds were welded to the head of a 6-in. 100-lb. T-rail. The bond heads were sheared in an Olsen universal testing machine of 200,000 lb. capacity. The results were as in Table II.

Table II—Shearing Strength of Silicon-Copper and Pure-Copper Bonds		
Type of Rod	Number of Tests	Average Shearing Strength, Lbs. per Sq. In.
Silicon-Copper.....	8	27,062
Pure Copper.....	6	17,380

The use of the silicon-copper welding rod increased the shearing strength of the bond head about 55 per cent. This increase in shearing strength of the weld is

**Fig. 3—Laying in the First Layer of Metal**  
The special electrode is used as shown and the metal deposited and welded to the rail. The arc used is about  $\frac{1}{4}$  in. long.

**Fig. 4—Welding Copper Wire to Deposited Metal**

In this step the first layer of copper is attached to the cable. This is done by directing the arc at the head of the bond near the rail flange.

attributed to the elimination of porosity and to the general improvement in the union between the copper and steel.

The improvements in bond design have been accomplished largely through results of tests made by a specially constructed fatigue-testing machine. If bonds were placed in service in order to obtain an estimate of their fatigue life, much time would be required and the nature of the test would vary from one joint to the next.

In order to arrive at a proper bond design, it was deemed advisable to standardize a test and to construct a machine which would test the bond under the most severe conditions. The proper cable length, arrangement of strands, proper protection of the strands where they unite with the weld metal, etc., are all factors which are of vital importance in bond design.

The test was made as follows: The bond terminals were welded to steel plates which were attached to vertical arms actuated by cams on a rotating shaft. The position of the bond was similar to the position which it occupies relative to the rail in service. The maximum vertical relative displacement of the two heads was  $\frac{11}{16}$  in. which corresponds to an extremely severe service condition,—one, in fact, which seldom, if ever, exists.

The original all-copper bond has been greatly improved by the addition of a copper sleeve or skirt which gives a fillet effect to the bond where the strands unite with the weld metal. The fatigue stresses are distributed rather than concentrated at the strand-to-bond head union. Copper was found to be the best material

**Fig. 5—A Completed Weld of Copper**

By advancing the arc over the entire area and melting down the bond head the molten copper is washed up against the web of the rail and the weld completed in about 35 sec.

for this protective skirt. The test has also made it possible to determine the best cable length and arrangement of strands. The improvements brought about by the addition of the copper skirt and by increasing the length of the original 6-in. 4/0 bond one inch is shown by Table III.

**Table III—Fatigue Test of Bonds With and Without Protective Skirt**

Type of Bond	Number Tested	First Strand Failure Vibrations	50 Per Cent Failure Vibrations
6-in. 4/0 Bond without Protective Skirt.....	2	220,500	420,000
7-in. 4/0 Bond with Protective Skirt.....	2	660,000	3,000,000

In passing over the rail gap, the car wheels strike the rail they approach with considerable impact. The magnitude of this impact is dependent upon the width

**Fig. 6—Bonds Tested Under Severe Conditions**

This machine consists of two cams which stress the bond and cable under conditions more adverse than in actual operation.

of the gap, the alignment of the rails, the surface alignment of the track and the general condition of the joint structure and roadbed. Cupped rails increase this pounding considerably. As the rail flange is in tension, failure would be likely to start in that member if it is weakened at all by the application of a bond.

In order to determine whether or not the welding of base bonds by the copper electrode process damaged the rail, the following test was devised: A weld was made at the center of a 25-lb. mine rail on the base near the web. The position of each weld and the size of the rail was the same in each case. The rail was then placed head up on a span support of 24 in. The supports consisted of rails placed on heavy oak blocks. The rail was subjected to the blow of a 250-lb. hammer falling 28 in. The hammer struck the center of the rail head directly above the weld.

The results of these tests are shown in Table IV.

**Fig. 7—How the Copper and Steel Are Joined**  
A homogeneous mass of copper forms intimate contact with the steel of the rail and produces a contact having low electrical resistance.

The results in Table IV show conclusively that the process used in welding all-copper rail bonds does not injure the rail. This is attributed to the fact that in welding silicon-copper to steel, the arc is not directed at the rail, but plays upon the molten copper. By this process, the heat is distributed rather than concentrated. Naturally, the residual internal stresses are much lower, and there is no notching effect under impact. The results obtained with the carbon-arc process and copper-electrode process are practically identical. The fact that a new 25-lb. bonded rail withstood five hundred 28-in. blows of the 250-lb. hammer and did

not fail after a deflection of  $\frac{11}{32}$  in. is convincing evidence of the quality of the copper-electrode weld.  
The rail joint is subjected to flexural as well as to impact stresses when the wheel load passes over the rail between ties. This stress becomes a maximum when the application is at a point midway between ties. In order to determine the resistance to flexural stresses of a mine rail with a copper-to-steel base weld, a special test was made. A 4/0 bond head was welded at the

**Table IV—Impact Test of Bonds**

Type of Bond	Number Tested	Average Number of Blows	Average Final Deflection	Type of Rail
4/0 base Bond Copper-electrode Weld on Rail Base. New Process.....	3	500	21/32 in.	New 25-lb. rail
4/0 base Bond Copper-electrode Weld on Rail Base. New Process.....	3	100	5/16 in.	25-lb. rerolled
4/0 base Bond Carbon-arc Weld on Rail Base. New Process.....	3	100	$\frac{1}{2}$ in.	25-lb. rerolled rail
Rail with No Bond.....	3	100	7/32 in.	25-lb. rerolled rail

Note:—Failure did not occur in any case.

center of the rail on the base near the web. The rail was then placed head up on two steel supports with a span of 24 in. The load was applied at the center of the rail head directly above the bond head. Each specimen was given a maximum deflection of 2.6 in. Half of the specimens were welded with the carbon arc and half with the copper electrode. The results are indicated in Table V.

**Fig. 8**  
**Welding Stages**  
Excessive scale and rust are first removed in the usual manner by means of a file or wire brush. The alloy rod does most of the cleaning during the welding process. These illustrations show the equipment necessary for placing a 4/0 bond on the rail. When applying the bond the arc is directed upon the molten copper and the heat is thereby distributed rather than concentrated in a manner that would cause injury to the rail. The mold confines the heat and thereby aids in facilitating the application of the bond.

The severity of this test may be realized from the fact that measurements showed the width of the rail base and the rail height to have been reduced about  $\frac{3}{8}$  in. at the point where the bend occurred.

It is interesting to note that the percentage of failures of the unbonded and bonded specimens of rail

Table V—Test of Bonds Under Flexural Stress

Type of Bond	Number of Tests	Number of Failures	Percentage of Rail Failures
4/0 base bond, copper-to-steel type, welded to rail base by new process.....	36	4	11.1
Rail with no bond.....	12	1	8.3

were of the same order of magnitude. It is, therefore, fair to assume that the failures of the bonded specimens might have occurred if the rail had not been bonded. Considering the magnitude of the deflection, which is out of proportion to what actually occurs in service, the conclusion may be readily drawn that rails with all-copper bonds welded to the base, are practically unaffected by the welding.

## Darco, a Boneblack, Is a New Product of Lignite

Large Plant, Owned by Powder Company and Located in Texas Lignite Field, Will Make Sugar-Refining Charcoal

BY HOWARD C. MARSHALL  
Austin, Tex.

WITH the recent reopening of the \$1,000,000 plant of the Darco Corporation of Wilmington, Del., a subsidiary of the Atlas Powder Co., with a plant and mines at Marshall, Tex., lignite coal will be put to an entirely new use. The Darco plant is the largest establishment in the world for the making of decolorizing and deodorizing carbons from lignite coal.

Darco is a product new to the commercial world. Briefly, it is a decolorizing and deodorizing carbon which its manufacturers claim will take the place of boneblack in the refining of sugar. Its manufacturers claim that it will eventually replace that substance because it can be produced at the Marshall plant much cheaper than other sugar-clarifying agents.

Boneblack is a charcoal made by burning crushed bones. It purifies sugar liquids in the same way that a gravel filter will purify water, only much more thoroughly. The main steps in the manufacture of Darco are: First, the crushing of the lignite; second, the retorting of this crushed product to drive off the volatile gases; third, the treatment with hydrochloric acid to eliminate the ash. When ready for use, Darco and boneblack are much alike in texture and general appearance.

One of the big commercial advantages which the Darco manufacturers will have over their boneblack competitors is the fact that whereas bones are collected from all over the world and transported to the burning plants, the Darco raw product, lignite, is at the very door of the factory.

At the present time, the Darco Corporation owns 300 acres of lignite land ten miles south of Marshall, and holds option on several hundred additional acres. It has been estimated that there are approximately

10,000,000 tons of lignite in the company's holdings, practically all of which is of the proper quality, and is easily accessible for mining and manufacturing of the Darco. The estimated capacity of the big plant at Marshall is 150 tons of raw lignite daily, from which 25 tons of finished product can be made.

At present, the plant of the Darco Corporation consists in more than ten buildings, which cover a total area of 66,000 sq.ft. It is situated just outside the city limits of Marshall on a site of 85 acres, and on the main line of the Texas and Pacific R.R. The plant is served by approximately 3,200 ft. of track, over which the raw materials are brought in, and the finished product is shipped out.

Automatic conveying and handling devices are employed in the buildings, all of which are of fireproof construction. From the moment the raw materials is dumped from the cars until it emerges in neatly sealed and standardized packages of Darco it is handled entirely by machinery.

Babcock and Wilcox boilers and a 600-kw., turbo-generator equip the power house, which is itself of brick-and-steel construction. Superheated steam is generated in these boilers at 200 lb. pressure, passed through the turbo-generator, and then is carried at low pressure to the main plant where it is used in process work, thus generating electrical energy at low cost.

R. E. Demmie, a Belgian chemist, for a number of years conducted experiments with lignite coal, at Homer, La., looking toward the discovery of a new decolorizing and deodorizing agent to be used in the refining of sugar. He succeeded in interesting the Atlas Powder Co. of Wilmington, Del., in his experiments. A small experimental plant was constructed at Homer, and here it was proven that Mr. Demmie's discovery, Darco, could be made a commercial success.

Three things were essential to the place where the big plant should be built: Adequate transportation facilities, cheap fuel, and nearness to the raw product, lignite of a particular variety. Marshall had the transportation requirements, and it could get the fuel, natural gas. But at the time, it did not know that it had the lignite. More than two hundred test wells were sunk, and it was found that surrounding Marshall, particularly about ten miles to the southeast of the city, was one of the largest and richest lignite fields in the world. The actual discovery of the big field was made by Mrs. W. C. Martin, of Dallas, Tex., who was engaged in sinking a number of water wells on her ranch property in the Sabine River bottoms.

A 10-in. gas main was promptly laid from the Bethany-Elysian fields. This line can carry 20,000,000 cu.ft. of gas every twenty-four hours. It is estimated that the gas fields can produce a capacity of 100,000,000 cu.ft. of gas daily. The industrial gas rate is as low as 7c. per M. ft., this giving Marshall, it is believed, the lowest industrial gas rate in the Southwest. Domestic consumers of gas are supplied by the Texas Co. from another field.

The final consideration in the selection of Marshall was the fact that the city is approximately one hundred and fifty miles from Beaumont, two hundred miles from Houston and Galveston, and three hundred miles from New Orleans. The main difficulty which the Darco people have experienced so far, and will continue to experience, is getting the refineries divorced from the age old boneblack process.

# News Of the Industry

## Old Parties Would Boost Union Output To Nullify La Follette's Power

**Fear, Unemployed Miners May Vote for Third-Party Candidate—Increase in Work Likely to Influence Workers in Other Industries—  
Need of Statistics Emphasized**

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

A major effort is being made by each of the old parties to stimulate employment of coal miners in the union field. Unless some means can be devised to increase production in the Central Competitive region it is feared that many of the coal miners out of employment will vote for Senator La Follette for President. It is true that the returns to the U. S. Employment Service from Ohio, Indiana and Illinois show no significant amount of unemployment, but it is admitted there is large concealed unemployment in those states. This term is used at the Labor Department to indicate employment at a wage substantially less than the worker is capable of earning at his own vocation. The discontent engendered by employment under such conditions is almost as great as that which accompanies unemployment.

Since each of the parties is convinced that a majority of mine workers vote with it under normal conditions, there is a general desire among leaders to devise some means of increasing coal production in the doubtful states. While Illinois is not regarded as doubtful, there is the greatest uncertainty as to the political situation in Indiana and Illinois. There also is the consideration that the employment of a greater proportion of the coal miners will influence labor engaged in their pursuits. While each of the parties is equally anxious to do something to increase coal-mine employment, the Republicans happen to be in a position to accomplish more in that direction through their possession of the machinery of the federal government.

### Abandon Plan to Cut Wages

Two ways of increasing employment have been given consideration. One is the reduction of the union scale in the hope that this would reduce costs to the point where many mines could compete with the non-union product. The other is to induce consumers to increase their purchases. Since the politicians in charge of the campaign work are not thoroughly acquainted with the coal business, their first thought was that a reduction in the

wage scale would be all that is necessary. Since then they have been told that this would not necessarily increase employment to any great extent, as any cut in the union wage would result in a corresponding reduction at non-union mines. While it now is recognized that a reduction in the scale might not be productive of a great increase in employment there still is considerable sentiment in favor of such action. Some are of the opinion that the union leaders in their hearts would like to see this done, as it would make easier their task of extending their organization. It is known that a determined attempt is being made to win back some of the ground lost in Kanawha, New River and other fields. Wage levels in the non-union field already have reached the point where some complaint is being heard. If they were forced to new low levels by a reduction in the union scale, it would increase union sentiment.

### G. O. P. Would Speed Output

So far as the Republicans are concerned chief reliance seems to have been placed on an effort to speed up consumption. Some are unkind enough to say that the recent official pronouncements urging early coal purchases had a political motive. Whether or not that be the case it is declared that the word is being passed around to large industries that there is no better way to increase the Republican party's chance of success than to store coal at this time. It is being pointed out that here is a perfectly legitimate way to help the party and at the same time, in view of the probability of a severe winter, to take a prudent business step. Since this objective meets the thorough approval of the Democratic leaders, it is anticipated that they as well will encourage early buying of coal.

Incidentally, this movement does not have to exaggerate the situation to prove the advisability of coal purchases at this time. While it is unfortunate that the stock report cannot be made available before the first week in October, the figures covering production during the first eight months of the year now are available. Performance during the past two months has been

disappointing and has pulled down the year's average.

A month ago it seemed probable that 1924 production would aggregate 455,000,000 tons. It now has been necessary to revise that estimate downward. Even allowing for the average seasonal increase, it is difficult to figure how the 1924 production can exceed 442,000,000 tons. The lowest conservative estimate which has been made of 1924 consumption is 480,000,000 tons. Even if that low estimate is correct the probabilities are that stocks will not exceed 20,000,000 tons. Were the country's reserve to be reduced to that point, conditions would be ripe for a runaway market on any slight scare.

If 1924 production should not exceed 442,000,000 tons the extent of the depression in the industry can be realized in view of the fact that it is necessary to go back to 1911 to find a normal year with production at a lower rate. Production was lower, of course, in 1921-1922 because of post-war deflation and in 1914-15 because of the paralysis following the outbreak of the European struggle.

### Coal Statistics Needed

This entire situation emphasizes again the need for more coal statistics. It can be stated on high authority that more is known of nearly any other important commodity than is known of coal. It is true that the forthcoming stock report will meet the most crying need of the immediate situation, but before the coal business can be conducted entirely in the light much more should be known of distribution and consumption, to say nothing of statistics covering various other important phases of coal production and distribution.

The hope is entertained that the difficulties now being experienced by the political leaders in learning enough of the situation to determine how they may be able to increase coal-mine employment and be rewarded by grateful voters may bring home to those who have influence in legislative matters the need for additional appropriations for coal statistics, or at least statutory authority which would allow government bureaus to receive contributions from the industry for the purpose of augmenting the funds which they have at their disposal for statistical purposes.

In reporting on the application of the Coal River & Eastern Ry. for permission to extend its line to Prenter, W. Va., a distance of 11 miles, Interstate Commerce Commission Examiner C. E. Boles advised against granting the application.

## 152 Miners Killed in

### Mine Accidents in July;

7 Months Total Is 1,458

Accidents at coal mines in the United States during July, 1924, caused the death of 152 men, or 58 less than the number killed in July, 1923, according to information received from state mine inspectors by the U. S. Bureau of Mines. The production of coal during the month was 40,066,000 tons; hence the fatality rate was 3.79 per million tons of coal mined. This rate is lower than that for the preceding month (4.22) as well as for July last year (3.92), and it is about 10 per cent lower than the average rate (4.20) for July during the ten-year period 1914-1923. For bituminous mines alone the reports showed 112 deaths and a fatality rate of 3.47 per million tons, as compared with a rate of 3.55 for July last year and a ten-year average rate of 3.82. For anthracite mines alone, the number of fatalities in July, 1924, was 40 and the fatality rate was 5.14, as compared with 6.01 for July last year and a ten-year average rate of 6.36.

The accidents during July brought the total number of fatalities during the first seven months of 1924 to 1,458, as compared with 1,478 during the corresponding months last year. Because of the explosions during the present year and the lower output of coal, the fatality rate for 1924 to the end of

### Dominion Coal Co. Plans Equipment Financing

The directors of the British Empire Steel Corporation are seeking authority from the preferred shareholders of the Dominion Coal Co., a subsidiary, for an issue of \$15,000,000 of the coal company's bonds to provide further working capital and equipment, according to advices from Montreal. The new bond issue would be used to refund the \$4,988,000 outstanding bonds and provide \$5,000,000 to meet the existing indebtedness due to capital expenditures, and the balance would be issued from time to time for further capital expenditures.

When the preferred stock of the Dominion company was issued in 1905 it was provided that no new mortgage could be placed on the properties without the consent of 51 per cent of its stockholders. The president states that the new issue will put the shareholders in an advantageous position for the resumption of dividends.

July was 4.65 per million tons, about 19 per cent higher than the corresponding rate (3.91) last year. The increase in the fatality rate was entirely in the bituminous industry, as the rate for anthracite mines actually declined from 5.66 to 5.49, while that for bituminous mines rose from 3.58 to 4.48.

## Tardy Coal Buyers May Run Afoul of Car Shortage

While the railroads of the country appear to be in excellent condition to handle the fall crop movement, in the opinion of Secretary Hoover, there may be more or less slight conflict with coal movement, the Secretary stated last week in discussing the subject, owing to the fact that many consumers appear to have disregarded the advice to lay in their stocks during the summer. The Secretary, however, did not predict a car shortage as a certainty, touching upon the subject only in a general discussion.

The Department of Commerce issued its appeal to fuel consumers three months ago to lay in their winter supplies of coal during the summer months, Secretary Hoover said, in order to forestall congestion in transportation when cold weather arrived, in order to level operating time at the mines and in order that consumers might benefit from the lower prices of summer. If a car shortage develops, it inevitably means higher prices for coal, he pointed out. Coal this summer has been cheaper than since 1916, Secretary Hoover said, adding that in his opinion some bituminous coal has been sold at a loss. The advice to stock during the summer was heeded by many consumers, the Secretary said, but was disregarded by many more, as evidenced by the fact that coal production this summer has been at the lowest rate in years.

## Coal-Mine Fatalities During July, 1924, by Causes and States

\*Gas explosion.

## Scotts Run Mines Resume On Open-Shop Basis

The Brady-Warner Coal Corporation last week posted a notice announcing that operations at Osage mines No. 1 and No. 2, near Morgantown, W. Va., in the Scotts Run field, would be resumed Tuesday, Sept. 2, under the 1917 wage scale. It has been stated that the mines will be run on an open-shop basis. The Osage mines are rated as having a capacity of 1,600 tons daily and it is stated that this can be increased to 2,000 if necessary. The company has 67 miners' houses at the mines, 62 of which are now occupied by miners formerly in the employ of the company, before it closed its Osage plants last spring after declining to renew its agreement with the union. It is stated by Superintendent Warren Cook that the order calls for the miners either to go back to work or else vacate the company houses.

The 1917 wage scale calls for 63c. a ton for room coal and 69c. for entry coal. The scale for drivers and motor-men is \$4.52 for eight hours, although at one time the operators gave these men \$1 more.

The agreement between the company and the miners now occupying the houses belonging to it stipulates that if for any reason whatsoever the coal company desires the houses in which the miners live, the miners must vacate on five days' notice, but if the miners leave the employment of the company or are discharged they may be removed at once.

It has been predicted by various coal operators in the Monongalia field that if the Brady-Warner corporation opened its mines at Osage on the open-shop basis several other mines along Scotts Run now closed would open on the same basis.

Officials of the United Mine Workers in the Monongalia field declare that they will remain in the field until it is organized 100 per cent for the union.

## Keen Competition Marks Bids On Navy Coal

Keen competition marked the bidding on 8,000 tons run-of-mine bituminous coal for delivery at the navy supply depot, South Brooklyn, N. Y., between October and May next. Proposals were opened by the Bureau of Supplies and Accounts of the Navy Department, at Washington, Aug. 29, when twenty-one bids were received, as follows:

A. K. Althouse Co., Philadelphia, \$5.34 per ton; W. H. Bradford & Co., Philadelphia, \$5.42; Brinker Coal Co., Johnstown, Pa., \$5.81; Davis Coal & Coke Co., Baltimore, \$6.05; Dexter-Carpenter Coal Co., Inc., New York, \$5.57; Eastern Fuel Co., Pittsburgh, \$5.55; Empire Coal Mining Co., Philadelphia, \$6.03; Fallen Timber Co., New York, \$5.35; Fidelity Coal Mining Co., Philadelphia, \$5.65; H. B. W. Haff, New York, \$5.92; George D. Harris & Co., New York, \$5.98, alternate bids \$5.71 and \$6.05; Imperial Coal Corporation, New York, \$5.97; W. A. Marshall Co., New York, \$5.93, alternate bid \$6.16; Morrisdale Coal

Wide World Photos

C. P. White

New head of the coal division of the Department of Commerce. Mr. White's wide experience and knowledge of the coal industry are expected to be of great help in building up the influence of the division.

Co., Philadelphia, \$5.87; Pattison & Bowns, Inc., New York, \$5.94; Patton Coal Co., Fairmont, W. Va., \$5.99; Seaboard Fuel Corporation, Philadelphia, \$5.99; J. Tatnell Lea & Co., Philadelphia, \$5.49; Titan Fuel Corporation, New York, \$5.88; Weston, Dodson Co., Inc., Bethlehem, Pa., \$5.98; West Virginia Coal & Coke Co., Elkins, \$5.68.

## Steel Industry Speeds Up

Not since the early days of the year has steel demand been so brisk as it is now. Plans are announced for the reopening of mills and furnaces and the prospect is bright.

There is every indication that one of those rare periods in which all the railroads seem to turn buyers at the same time is in prospect. There is already in the market inquiry for between 150,000 and 200,000 tons of rails, and at least 250,000 tons of business is expected to be realized in the next few days. Southwestern roads thus far have done most of the shopping, although Eastern lines are beginning to come in. As yet the Western roads have not come into the market.

One of the best indications of the trend is the announcement that the United States Steel Corporation will reopen the largest rail mill in the world, located at Gary, the day after Labor Day. This mill has been idle for two months.

The railroads are not the only present buyers, however. Practically every consumer of steel products, with the single exception of automobile builders, is in the market with a buying zest that has not been experienced for some time. Farm implement makers are especially active, and considerable tonnage is being taken by makers of tanks and stoves.

## Chemists to Discuss Fuels At Cornell University

In the issue of Aug. 21, p. 263, *Coal Age* published an account of the meeting of the American Chemical Society to be held at Cornell University, Sept. 8-13. The program has been revised and lengthened, as follows:

Wednesday afternoon, Sept. 10, Rockefeller Hall—(1) F. W. Stevens, "The Rate of Flame Propagation and the Mass Law" (lantern); (2) R. T. Haslam, W. G. Lovell and R. D. Hunneman, "Radiation from Nonluminous Flames" (lantern); (3) F. W. Sperr, Jr., "The Present Trend of the Manufactured Gas Industry"; (4) N. H. Memory, "Notes on Continuous Vertical Retorts"; (5) R. T. Haslam, F. T. Entwistle and W. E. Gladding, "Reactions in the Fuel Bed" (lantern); (6) R. T. Haslam and E. L. Chappell, "The Measurement of Temperature of Flowing Gases" (lantern); (7) T. E. Layng and W. S. Hathorne, "The Determination of the Temperatures of Plasticity, Maximum Pressures and Solidification of Coking Coals" (lantern); (8) H. J. Rose and G. G. Desy, "Composition of the Volatile Matter Obtainable from Coke" (lantern); (9) T. E. Layng and W. S. Hathorne, "An Examination of the Methods of Analysis of Fuel Gas" (lantern); (10) E. C. Freeland and W. G. Harry, "The Use of Alcohol and Alcohol-Ether Mixtures as Motor Fuels"; (11) S. W. Parr and W. R. King, Jr., "The Density of Carbon Dioxide with a Table of Recalculated Values" (lantern); (12) Jerome J. Morgan and Merl H. Meighan, "An Investigation of the Caustic Soda Process of Extracting Low-Temperature Phenols."

Thursday afternoon, Sept. 11, Storage of Coal and Spontaneous Combustion; S. W. Parr, Chairman—Discussion started by (1) S. W. Parr and R. T. Milner, "The Oxidation of Coal at Storage Temperatures" (lantern); (2) S. W. Parr and E. R. Hildgard, "The Oxidation of Sulphur as a Factor in the Storage of Coal" (lantern); (3) S. W. Parr and C. C. Coons, "Carbon Dioxide as an Index of the Critical Oxidation Temperature for Coal in Storage" (lantern); (4) S. W. Parr, "Deterioration and Spontaneous Combustion of Coal in Storage" (lantern); (5) N. R. Beagle, "Deterioration of Midwest Coals under Different Storage Conditions—Effect on Burning Qualities"; (6) J. D. Davis and John F. Byrne, "Spontaneous Combustion of Coal—Characteristics Shown by an Adiabatic Calorimeter" (lantern).

The coal consumed by different manufacturing enterprises during 1923, as shown by the Department of Commerce, is as follows: Watchcase manufacture, 16,427 tons; baking powder and yeast, 246,963 tons; boot and shoe findings, 25,626 tons; bicycles, 25,505 tons; phonographs, 158,047 tons; motorcycles, 12,504 tons; glue and gelatine, 424,845 tons; paper bags, 19,641 tons; engraving plate printing, 3,100 tons; engravers' materials, 910 tons; cast-iron pipe and fittings, 170,497 tons; leather belting, 9,604 tons.

## Urge Safety Inspector for Each Anthracite Colliery

Scranton, Pa., Aug. 29.—A safety inspector for every colliery in the anthracite region is the desire of the Anthracite Safety Council as expressed in resolution form at a meeting in the Glen Alden Coal Co. offices in this city on Aug. 27. Copies of the resolution indicating the attitude of the council are to be printed and mailed to every operation in the region.

The resolution which provides for the safety inspectors specifies that the man appointed to such a position at each colliery must have had at least ten years experience in mining. He is to have authority to enforce discipline relative to mine laws and company rules. At the end of each work day the safety inspector will meet with the colliery superintendent, mine foreman, or assistants and representatives of the miners to discuss local conditions, according to the resolution. The inspectors would be paid by the coal companies.

P. J. Moore, state mine inspector for the Second District, presided at the meeting of the safety council. John R. Bryden, of the Pancoast Coal Co., acted as secretary. Others in attendance were August McDade, Jenkin T. Reese and Llewellyn Evans, state mine inspectors; T. J. Williams, of the Glen Alden Coal Co.; H. T. McMillan and J. Palmer, of the Pennsylvania Coal Co.; John Corcoran and Thomas Shrive, of the Jermyn Coal Co.; Morgan Davis, of the Mt. Jessup Coal Co., and James Gleason representing the United Mine Workers. The miners' local unions are to receive copies of the resolution and consider the advisability of the adoption of such a move.

The meeting was the third within the past three months for the purpose of devising ways and means of reducing fatal as well as minor accidents at the mines.

## Conciliation Board Urges \$5 Scale in Alberta

The report of the Board of Conciliation appointed under the Industrial Disputes Act to investigate the dispute between the coal operators of northern Alberta and the Edmonton and District Mining Federation recommends the following scale of wages:

Miners on company work, \$5 for an eight-hour day; brushers, track layers, drivers and chief cager, also \$5 a day; pushers and assistant cagers, \$4.50 a day; coupler (under 18 years), \$3.50 a day; assistant track layer, \$3.50 a day; boys under 18 on surface, 35c. an hour; outside labor, 50c. an hour; blacksmith, 65c. an hour.

The miners asked \$5.60 per day. The operators in the dispute were prepared to pay \$5 per day.

The board recommended that contract rates in the different mines be continued as they were in the agreement that expired on June 30, 1924, with provision for no overcrowding of contract miners during busy seasons.

Some of the independent mines in Alberta are now working, having effected an agreement with their men, and are shipping coal to Winnipeg.

## H. F. Randolph, Well Known Electrical Engineer, Dies

Harry Fitz Randolph, widely known in the coal industry as an electrical engineer, died at Mt. Hope, W. Va., Aug. 23, 1924. He was born at Johnstown, Pa., in 1871, and was educated at Swarthmore College and Johns Hopkins University. After graduation he immediately entered the students' course of the General Electric Co., Schenectady, N. Y., and after completing the three years' work required, was employed by the Yough River Coal Co. at Scott Haven, Pa., as chief electrician. When this company was merged with the other constituent companies forming the Pittsburgh Coal Co.

Harry Fitz Randolph

Mr. Randolph was retained as electrical engineer. He was later made assistant manager of mines, which position he retained until 1910, when he went into consulting work with George Wood as the Wood-Randolph Co. at Pittsburgh, Pa. Reorganization in 1912 changed the name to the Randolph-Means Co., which arrangement endured until 1917, since which time he had maintained an engineering organization under the name of Harry F. Randolph. During his professional career Mr. Randolph was retained by many large coal mining corporations throughout the country, notably the New River Co., Macdonald, W. Va.; H. C. Frick Coke Co.; Logan County Coal Corporation, Lunda, W. Va.; Wayne Coal Co. and Union Collieries Co. He had also been retained by the Department of Mines of Pennsylvania, Department of Mines of West Virginia and Federal Bureau of Mines.

### Escaped Johnstown Flood

He was a survivor of the Johnstown flood in 1889, in which his oldest brother was lost. Mr. Randolph was a member of the Engineers Society of Western Pennsylvania, the American Mining Congress, the American Institute of Electrical Engineers and other scientific organizations.

## Brophy Scoffs at Plan For Prosperity Through Less Money for Miners

"Give the miners less money and make their community more prosperous! This is, in substance, the theory many coal operators are now advancing, by the constant issuance of 'wage adjustment' propaganda. This is especially true of Central Pennsylvania Operators, Charles O'Neil acting as their press agent," said John Brophy, president of District 2 (central Pennsylvania), in commenting on the statement issued by Mr. O'Neil following the meeting of central Pennsylvania operators, at Altoona, Aug. 22.

"Coal production has been at the lowest level in years," said Mr. Brophy. "Consumers are not buying coal. Operators are not able to sell coal at any price because consumers do not want coal and will not buy it until they need it. Coal prices are now down to the lowest point in many years, still there is very little market.

"The reason for the operators' frantic efforts to set aside the present contract is therefore obvious to any one who dares to look into the matter. They are seeking to bring about a wage reduction when business is poor, so that when business improves and they are able to sell their coal they will make larger profits by reason of the reduction in wages to their employees.

"Mr. O'Neil's statement quotes many figures. He has counted up every hole in the ground that ever produced a bucket of coal and employed a couple of men to get his grand total of idle mines in District No. 2. The U. S. Geological Survey figures are just as reliable as Mr. O'Neil's (with the odds in favor of the Survey). If the Survey does not report the number of idle mines in the union fields, neither does it report the number of idle mines in the non-union fields, which fact Mr. O'Neil carefully fails to state.

"Mr. O'Neil is very much in error when he quotes the district officers as saying that the International officers are responsible for high wages in the union fields and low wages in the non-union fields. The International and the district officers are in complete accord on the wage question and I have told them that wage reduction is not a remedy for slack work; that wage reductions in the union fields mean further reductions in the non-union fields, and the result is no change in the relative position of the different districts, but it does mean less earnings and more poverty for the miners. The operators would not be benefited, but the mining communities would suffer more because the miners would suffer more.

"In March the operators were voluntary signers to an agreement for a three-year period. The ink of their signatures was scarcely dry before they started what might be termed an 'educational campaign' through the newspapers to sell the wage-reduction idea.

"The United Mine Workers have not been deceived by these specious arguments, but knowing their fallacy, intend to hold the operators to the Jacksonville agreement."

## Western Kentucky Mines Unable to Open On Non-Union Basis

Scheme Proves Abortive When Miners Stay Away—Failure of "Invitation" to Workers Attributed to Garbled Story in Louisville Newspaper—Plan Called Fight Against Union

Efforts of the western Kentucky coal operators to reopen the mines in the strike zone of District 23, on Aug. 25 failed completely. No workers showed up when the mine whistles were blown, following posted notices and letters mailed to the workers. Reports indicate that at most of the mines no men reported for work, groups forming in some cases to see whether there would be anyone reporting. Indications are that some workers would have reported except for fear of personal violence.

Operators of the section assert that the effort was largely frustrated through the activity of a Louisville newspaper, which got wind of the plan, obtained a garbled report, and came out with a headline article indicating that the operators had arranged to fight the miners and the union. It is asserted that when copies of the paper reached the central Kentucky district the workers went up in the air, and the good work of months was destroyed immediately, as the story merely made the workers mad. The word "fight" as used indicated to workers that an effort would be made to run, to destroy the union, import non-union men, and use every legal effort, even to guns and bayonets, if necessary.

The operators merely offered the 1917 wage scale and an opportunity to work if the strikers desired to do so. It was felt that after more than four months of idleness many workers would be glad of a chance to return to work, especially in view of the fact that there has been a considerable amount of complaint over strike benefits paid by the union.

The operators have steadfastly endeavored to show the workers that the Jacksonville agreement was to the detriment of the west Kentucky field and that the field could not operate profitably on any such basis, give its workers steady work, and keep out of the sheriff's hands. An effort also has been made to indicate to the workers that they were being used to aid in forcing an agreement that would help the Illinois, Ohio and Northern operating sections in maintaining union gains, but which would mean idleness for western Kentucky except in periods of shortage and high prices.

The argument is made that at the Jacksonville conference it was openly stated that there were 200,000 too many miners in the country, too many mines, too much potential capacity, etc. The only way to better conditions for the national organization would naturally be to eliminate a lot of workers, and some of the smaller fields such as west Kentucky.

It is rumored in the field that the International has supplied only about \$7,500 in the way of strike benefits other than a fund of around \$50,000 loaned to District 23 and to be paid back later on, although the district

union has been in operation for many years and has paid large sums into the coffers of the International.

Just what the next move will be is a question. Apparently workers are of the opinion that with fall business close at hand the operators were bluffing in offering the 1917 scale and will make a better proposition later. There is a possible chance that the operators will modify their offer and propose the 25 per cent reduction that was offered at Louisville five months ago. It seems that some of the workers objected especially to the fact that the recent offer was not as good as that previously made, but the previous offer was made on the understanding that the mines would not close down.

Eviction proceedings have been started in some sections of the field at mines that have been able to resume with part of their old forces and which are now endeavoring to rid their camps of strikers who refuse to return to work.

It is reported from Henderson, Ky., that practically all of the mines in that county are again running, and on a non-union basis, the Southland Mining Co. having started on Aug. 21, with thirty men, working one section, almost twice that number reporting for work.

The eleven mines of the St. Bernard Mining Co. are all reported to be on a working basis now—non-union with an employees' benefit association—although they are getting only 40 per cent running time. These mines were turned non-union after they were absorbed by the West Kentucky Coal Co.

### Safety Council Has Meat For All Comers

Last week *Coal Age* detailed the program of the Mining Section of the National Safety Council Congress, to be held at the Hotel Brown and Seelbach, Louisville, Ky., Sept. 29 to Oct. 3. Reference also was made to the annual business meeting. However, there are some other meetings that have relevance to coal-mine operation which were omitted, namely, some general sessions and those of the health service and plant-publication sections.

At 2 o'clock Wednesday afternoon C. F. N. Schram, M.D., medical director, Fairbanks, Morse & Co., Beloit, Wis., will discuss "Industrial Health as a Purchasable Commodity"; Mrs. Frank B. Gilbreth, Montclair, N. J., "The Fatigue Problem in Industry"; A. W. Colcord, M.D., Carnegie Steel Co., Clairton, Pa., "The Health Education of Our Foreign Families"; C. L. Ferguson, M.D., Selby Shoe Co., "How to Make a Sanitary Survey of an Industrial Plant," and A. D. Pacini, M.D., Chicago, Ill., "Physiotherapy and Physio-logical Reconstruction."

On Thursday morning at 10 o'clock the employees' benefit association section will hold a session at which Dr. A. H. Ryan, professor of physiology, Tufts College, Mass., will discuss "Benefit Associations—Their Need, Scope and Possibilities"; J. E. Culliney, safety engineer, Bethlehem Steel Co., Bethlehem, Pa., will answer the question "Should the Management Have Anything to Say in the Running of a Mutual Benefit Association?" and Dr. Wade Wright, assistant medical director, Metropolitan Life Insurance Co., will consider the problem "Should Medical Service of a Mutual Benefit Society Extend Beyond the Work Done in the Plant?"

In the afternoon at 2 o'clock Dean K. Brundage, U. S. Public Health Service, Washington, D. C., will address the employees' benefit associations section on "Statistical Analysis of Sick Benefit Association Records," and Albert B. Tenney, president, Malden Electric Co., Malden, Mass., will discuss the question "Should Physical Examination Be Compulsory to the Members of a Mutual Benefit Association?"

A general session will be held Thursday afternoon at which C. B. Auel, Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., will discuss "Accident Records and How to Keep Them"; Frank Morris, Liberty Mutual Insurance Co., Boston, Mass., will address the audience on "Safety Committees Will Starve Unless Fed"; R. T. Solensten, bulletin editor, National Safety Council, will describe "How to Advertise the Big Idea"; H. O. Houze, personnel manager, National Malleable & Steel Casting Co. will show how to educate the workman, and Sydney W. Ashe, General Electric Co., Pittsfield, Mass., will detail "Personal Experiences with the Prone-Pressure Method."

On Tuesday evening both ladies and gentlemen will have a jollification party entitled "The Frolics of 1924," and on Thursday evening will be held the annual banquet with Herbert C. Hoover, Secretary of Commerce, as principal speaker, and an address on "The Responsibility of Leadership," by Dr. Augustus Dyer, Vanderbilt University, Nashville, Tenn. All these meetings will be at the Hotel Brown.

Nothing has been said as to the plant publications section, which meets in two sessions on Thursday, or the public utilities section, so near akin to the mining section, that meets on Tuesday, Wednesday and Thursday mornings, or as to many other sections of less interest to the industry. The plant publications section gives three prizes to the three best employees' magazines, of which there are more than three hundred, and to the companies presenting the best safety posters.

Seven motion pictures will be shown daily from 1 to 2 p.m. in the Hotel Brown, among others being "When a Man's a Miner," produced by the Bureau of Mines. Eighteen manufacturing concerns will exhibit safety appliances in the Hawaiian Building, opposite the Hotel Brown. It is probable that other mining meetings will be held to arouse an interest in safety in the west Kentucky field similar to those held in St. Louis recently.

## Practical Pointers For Electrical And Mechanical Men

### Motors Successfully Dried Out After Five Days Under Water

Although Submerged in Water All the Important Electrical Equipment  
Was Dried and Again Placed in Service Without a Mishap  
—One Motor Was Dried Electrically

**A**FTER being completely under water for a period of five days, five 1,000-hp. pump motors in the main pumphoom of the Glen Alden Coal Co., in Scranton, Pa., were successfully dried and placed back in service.

A flood from the Lackawanna River entered one of the collieries at the rate of 700,000 gal. per minute. The Hampton Water Shaft Pumping Station served this draining area with five centrifugal pumps, each driven by a 1,000-hp., 2,200-volt, three-phase, 60-cycle, 870-r.p.m. induction motor, four of which were Westinghouse motors.

In spite of the large capacity of the pumps, at the end of six hours, the pumps and motors were completely submerged. The water finally rose about 25 ft. over the tops of the motors.

It was five days before any of the pumps could be reached, and the pumps and motors were found half buried in mud and silt, several hundred tons of which had to be removed before any

#### Large Pumphoom

After the water was lowered, workmen entered the pumphoom and found the pumps and electrical equipment half buried in mud and silt. The motors had been in water five days, yet, when carefully dried out, all five motors were put back in service and gave no trouble. Note the large discharge pipes and how they were reinforced after the flood.

Some of the Largest Centrifugal Mine Pumps in the Coal Field Are Located in the Hampton Pumping Station

At this pumphoom all the water from five mines and most from three other mines is pumped to the surface. Each pump is driven by a 1,000-hp. alternating-current motor. This illustration shows the pumps in service after the flood. The pumphoom is the largest in the mining field. Power is supplied from one of the company's big generating plants located nearby. Incidentally, much of the mine water is used for cooling purposes in the power house.

of the pumps could be placed in operation. One by one the motors were disengaged from the pumps and taken outside, with the exception of one motor on the pump farthest from the entrance to the pumphoom.

These motors were disassembled, cleaned off with a fire hose, and dried in a temporary wooden inclosure built around them. This housing was open at the bottom and ventilated at the top, and a temperature of 90 deg. C. was maintained by circulating steam through coils of pipes inside the inclosure. This arrangement required little attention and gave a constant temperature.

The motors were dried in periods ranging from seven to eleven days until insulation resistance measurements showed a constant value for a period of twenty-four hours or longer. After being thoroughly cleaned out, painted, and the swollen slot wedges trimmed, the rotor windings were put back and the motors placed in operation again. They have been in service since that time and have given no trouble.

One motor which was left inside the mine was covered with a wooden house and dried by Westinghouse space heaters. Small fans gave the necessary ventilation. This job required closer attention and took longer to dry than

the other motors, but it obviated the necessity of taking the motor outside. The starting panels, oil switches, and all other apparatus were put in service after being cleaned and dried by blow torches and space heaters. The only failure of the entire outfit was a short piece of cable stretching from a bus-bar to one of the oil switches.

## Electrical Forge Saves Workman's Time

Anyone who has ever worked around an underground repair shop has no doubt often realized how inconvenient it is to make a repair when some part of the material had to be heated. Usually the workman finds that the part must be taken outside to the blacksmith shop.

If the mine has only one shaft it is frequently necessary to wait until the trammers can stop the hoisting of coal to let the workman get to the surface. Even when the material reaches the blacksmith shop there is often further delay if other work is being done in the fire.

### NO NEED TO BUILD FIRE

Repairs which must be made at night when the blacksmith's fire is out and a new fire must be started, and, moreover, by someone inexperienced with the forge, cause many troubles and dangers. Usually when the blacksmith comes to work the next morning he finds things misplaced, thus effectively lowering the efficiency and morale of the shop. Aside from these difficulties the losses occasioned by delays to the workmen and equipment can never be retrieved.

At the J. K. Dering Coal Co. mine, at Eldorado, Ill., the inside workmen who repair locomotives, cutting machines and other mine equipment have often felt the need for some means of heating bent bolts and small machine parts. Old methods didn't suit them; when mining machinery has to be repaired all the work must be done quickly. When a man is under a locomotive it is no easy matter to crawl

from under it and back again for every little detail; this wastes time. While an assistant is going outside to heat and straighten a bolt, no man is going to wait in a cramped position in a dark, and sometimes wet, motor pit.

To obviate these delays and difficulties the workmen employed in the repair shop near the foot of the shaft at this mine have built their own forge. The unusual thing about it is that it operates by electricity supplied from the main trolley circuit. Every precaution has been taken to make it as safe as possible and in this respect it is different from most contraptions designed in coal mines.

### FREE FROM GAS AND SMOKE

When not in service the forge generates no gas or smoke to fill the workshop and make things disagreeable. It stands in a separate little room to the side of the shop.

The essential part of this forge is a barrel filled with salt water and provided with necessary protective equipment. The barrel is mounted on an insulated platform upon which the workman stands and keeps himself free from ground connections. The positive conductor from the trolley circuit first passes through a disconnecting switch located near the forge. On the end of this lead a metal plate has been fastened and placed in the bottom of the barrel. The negative conductor is attached to an insulated busbar fastened to the top of the barrel.

By insulating the platform from the ground and also insulating the negative conductor from all parts of the forge the whole equipment is made relatively safe. A workman standing on the platform does not get a shock if he touches the positive conductor. Only when the man touches the positive lead and the negative conductor directly would he get a shock.

### ROD ELECTRICALLY HEATED

Whenever a piece of metal, usually a bolt or rod, is to be straightened the workman holds one end of it in his hand or in a pair of tongs and lays it upon the busbar in such a manner that

the end to be heated can be lowered into contact with the salt solution. As soon as the metal touches the salt water the current flows from the positive conductor into the solution, then through the rod up to the busbar and to ground. The end of the rod quickly heats and a few blows with a hammer straightens it. In this way parts needing repair which would ordinarily be thrown away are often made as good as new and frequently broken parts are heated so that they can be welded together after being heated and thus easily repaired.

## Oil-Sealed Tank Prevents Compound from Drying

One of the greatest difficulties in an electrical repair shop is to keep the impregnating compound from drying overnight or from day to day.

The Madison Coal Corporation, of Illinois, makes most of its electrical repairs at its Glen Carbon plant. "Last year the shop effected a saving of over \$5,000 in labor and material by making nearly all its own armature and field coils and repairing its electrical apparatus," says Joseph Long, assistant general superintendent of the company.

### Self-Sealing Tank

A reservoir extends completely around the outside of the tank containing the impregnating compound. By excluding the outside air only a little of the compound ever dries or thickens.

The shop is equipped with many modern coil-winding and electric repairing machines.

This company has designed an oil-sealed tank. When parts soaked with impregnating compounds are placed in this tank they are airtight and so protected from drying. This airtightness is obtained by welding a ring-shaped reservoir at the top of the tank and filling it with oil. When the cover is put in place the edge extends into the oil, and this traps the air in the tank and prevents its circulation and the entrance of other air.

The tank stands in a handy place in the shop where a large armature or a number of coils may be easily dipped and carried to a baking oven located in a small addition to the building.

### Electric Mine Forge

Machine parts which must be heated are placed in contact with the negative busbar on the barrel and the salt water solution. A forge like this never smokes or generates gas. It is used on a 250-volt trolley circuit.

## Discussion

### Ten per Cent of Rock Dust May Raise Ash Percentage to Required Figure

Dr. Wheeler Did Not Say That Ten per Cent of Inert Material Would Suffice—Size of Coal Dust More Potent Than Is Fuel Ratio

By GEORGE S. RICE

Chief Engineer, Bureau of Mines, Washington, D. C.

THE thoughtful letter of John Walls, of Ensley, Ala., relative to rock dusting and watering, in your issue of Aug. 7, appears to call for some reply from me, as he refers to certain statements I have made.

First, regarding the statement attributed to Dr. Wheeler that an addition of 10 per cent of rock dust is well worth seeking, I feel sure, from my conversations with Dr. Wheeler, that he had in mind not 10 per cent of rock dust added to pure coal dust but its addition to road dust already containing 30 to 40 per cent of inert material, in which is included both ash and moisture. He intended to convey to his hearers the idea that the addition of 10 per cent of artificially made rock dust would make it improbable that an ignition of the road dust would take place if a source of ignition was present.

#### INVOLUNTARY ROCK DUSTING

It is characteristic that the road dust in most British mines will run high in ash content, due to the general use of the longwall method of mining and the relatively friable roof material, which, by dribbling, often becomes mixed with the coal dust on the roadways.

Even in American mines, the experience of the Bureau of Mines, from taking thousands of road-dust, rib-dust and timber-dust samples, is that the ash plus moisture content in certain places, for example near partings, rarely is less than 25 or 30 per cent.

I hope that this will make it clear to the correspondent that there was no thought in the mind of Dr. Wheeler that 10 per cent of rock dust added to a pure coal dust which would give less than 20 per cent of inert matter in the mixture would be of the slightest avail in preventing ignition or propagation.

As concerns the second point, the effect of the ratio of volatile matter on the relative explosibility of a coal dust, the correspondent has a generally correct idea of this but he must take into account two factors profoundly modifying explosibility:

(a) Some coals, like the splint coals of West Virginia and the subbituminous coals of the West, break into naturally coarse, more or less cubical particles. Other coals, such as the Pittsburgh district and the Pocahontas field coals, break down into structureless particles. In the former, a person

can go into the mine and come out relatively clean, but in the second coal, with the same amount of exposure, he gets quite black. Henry Walker, Chief Inspector of Mines of Great Britain, remarked to me that when he got very black in inspecting a mine, he told the management to look out for dangerous dust conditions.

#### HAVE 40 PER CENT 200-MESH DUST

(b) As to the quantity of the finest dust present in the rock dust or rib dust, it is the percentage of dust passing through a 200-mesh, which the Bureau has found is the best index of the danger of a bituminous dust, and this in the average sample ranges from 10 in the less dangerous dust to rarely over 40 per cent for the more dangerous dust. When coal is pulverized, so that practically all of it passes through 200-mesh, it responds almost directly in sensitiveness to the volatile-total combustible ratio, but the influence of the two factors already described may be superior to a difference in percentage of volatile matter. The effect of the coarser particles in the average mine dust makes the British permitted limit of 50 per cent in any part of the roadways a safe limit, as it must never be forgotten that this refers to the extreme limit and when a sample shows more than 50 per cent combustible, that locality must be rock dusted afresh. Also, you may be sure that, with a 50-per cent limit, the average analysis of road dust in that mine will show at least 60 and probably 70 per cent of inert material.

As regards the use of water, it is admitted that there is a difference of opinion on the application of water. Dr. Wheeler has proposed the use of water in combination with rock dust, but his explanation of this is that there must then be enough water to render the mixture incapable of ignition. However, this does not represent the requirement of the British law. We of the Bureau of Mines believe that there are grave dangers in a combination process through which by wetting, or use of water in the roadways, the rock dust is caked so it will not be brought into suspension by a concussion and thus neutralize the coal dust; and also the making of fresh dust along the roadways, which in general is more rapid in American mines than in European mines, due to our high-speed haulage, may thus deposit this coal dust

on top of the caked dust in sufficient quantity to ignite or to propagate an explosion.

On the third question raised by Mr. Walls, concerning the recommendation which I made for watering at the face, more especially in connection with cutter-bar machines, my views on this point are that it will help to lay the dust, as it is formed, and when loaded wet on the cars it will not be blown off as dry coal dust is, increasing the percentage of combustible along the roadway. There is another great advantage in watering at the face, that the miners do not have to breathe so much dust. This makes for their comfort.

A fourth point not brought up by Mr. Walls, but in another paper in the same issue of *Coal Age* and referred to in the editorial, concerns the moisture in the air increasing the violence of a gas or gas and dust explosion. The original statement by Dr. H. B. Dixon has, I think, been much misunderstood. He referred to explosion tests in absolutely dry air in comparison with those in moist air. Practically, there is always enough moisture in air to obtain the necessary chemical reactions of gases when ignition takes place.

I trust the foregoing explanation will help clarify the views of Mr. Walls and those of others who have referred to apparent inconsistencies in recommendations of the British authorities and of the Bureau of Mines.

Mr. Rice seems to suggest that we have been ill advised in reprinting for public consumption a truth that Mr. Rice assures us is too often quoted in error. We have rarely heard it quoted at all either erratically or in any other way. We are in fact not concerned about our part in its dissemination even if it is misquoted. First, because it is the truth, and secondly because if it is misapplied it serves to mitigate the evil of another truth far more often misquoted and misunderstood namely that water is helpful in reducing the violence of explosions.

We have often heard it said that if the air contains water vapor to the saturation point it will prevent an explosion. We have seen that statement in the proceedings of our national mining society. Seeing that, it seems well to point out that methane does not combine with oxygen direct but through aqueous vapor and the more water vapor the more rapid the reaction. The real value of humidified air is that it leaves the natural water of the mine dusts undiminished and in condensing adds to that moisture. As the quantity has to be so great that the dust when compressed in the hand will drip water we feel that there is some real danger in declaring the efficacy of humidification, for when incompletely performed it is not efficacious even though helpful. So perhaps, Mr. Rice, it is well to write the whole truth in *Coal Age*, the manner in which water vapor aids an explosion, the value of humidification and the risk accompanying imperfect applications of water. This we have done; we hope helpfully. EDITOR.

# Production And the Market

## Increasing Inquiries Intensify Confidence in Soft-Coal Market; Prices Recede Slightly

Despite a slight recession in prices and the customary pre-holiday tendency to hold off during the past week, a distinct note of optimism continues to pervade the bituminous-coal market. Favorable crop reports, bespeaking prosperity for the farmer, have been followed by indications that other industries have turned the corner with the appearance of buying for the replenishment of depleted stocks, which would seem to show that the long-awaited autumn upturn is under way. Improvement is especially marked in the iron and steel trade, where a notable feature of the recent brisk demand is the heavy buying of railroads, which in the last two weeks have been in the market for about 400,000 tons of steel. Even the textile industry, which has been particularly hard hit by the prolonged depression, is showing encouraging signs of a revival in activity, the change for the better in that field being scarcely less notable than that in the iron and steel trade.

### Volume of Inquiries Growing

The general improvement in business is reflected in a steadily increasing volume of inquiries in the soft-coal market, and while actual orders have not soared to any great heights, the evidence of interest on the part of consumers has served to restore a much-needed note of confidence.

Coal Age Index of spot prices of bituminous coal receded slightly during the past week, standing on Aug. 30 at 164, the corresponding price being \$1.99, compared with 165 and \$2 for the previous week.

A pronounced increase in activity took place at Hampton Roads, dumpings of coal for all accounts during the week ended Aug. 28 totaling 364,227 net tons, compared with 315,540 tons during the preceding week.

The movement of coal up the lakes is still far behind that of last year, but with the carryover from a year

ago and lower consumption probably will prove ample for all requirements.

Production of bituminous coal registered a striking gain during the third week in August, crossing the 8,000,000-ton mark for the first time since last March. The total output during the week ended Aug. 23, according to the Geological Survey, was 8,293,000 net tons, an increase of 384,000 tons over the previous week, when 7,909,000 tons was produced, according to revised figures. Anthracite production also reacted upward, 1,711,000 net tons having been produced during the week ended Aug. 23, an increase of 325,000 tons over the preceding week, when the output was 1,386,000 net tons.

A better tone pervades the anthracite market, retailers ordering more freely last week in a last-minute

move to take advantage of summer prices. The larger companies advanced mine prices of the larger sizes on Sept. 1, the increase averaging 10c. per ton. Independent quotations, however, are practically unchanged but firm. Stove coal continues to show the greatest strength in demand, though egg and pea show improvement. Steam sizes likewise are moving somewhat better and prices show a firmer tendency.

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

## Midwest Trade Grows

The Midwest coal trade feels distinctly better. There is nothing in the nature of a rush going on but domestic coals are shaking off their sluggishness and slight advances in some coals were attempted for Sept. 1. Franklin County 6-in. lump advanced from \$3 to \$3.25, egg from \$2.75 to \$3 and nut from \$2.35 to \$2.50. Screenings move in small quantities and remain at about the same price range they have occupied for weeks—\$1.60@1.75. No other price changes in Western coals were anticipated for Sept. 1. West Kentucky block held at \$2.40@2.60; 6x3-in. egg and 3-in. lump, \$2.25@2.40; No. 2 nut, \$1.75@1.90, and screenings, \$1.25@1.35. Indiana coals also were unchanged. No. 4 lump moves at \$3 and the other sizes trail Franklin County by 15 or 25c. No. 5 sizes maintain about their usual 25c. differential under No. 4.

In Chicago the retail trade in anthracite is picking up a little in anthracite as well as in high-grade bituminous. Hard-coal prices made their monthly wholesale advance of about 10c. which had its reflection in retail quotations. West Virginia smokeless continued its slow and steady movement into the Chicago district, with mine run maintaining its \$2 top price. So much of this coal has been

coming in all summer, however, that the domestic trade is not crying for it now.

In the Carterville field of Williamson and Franklin counties there is a noticeable movement of lump in the last week for domestic business, principally in the Northwest. Egg is just beginning to move a little, but nut and the other sizes are heavy and steam is going to be a problem in a short time when the mines show steadier work. Mines still get from 1 to 3 days a week in places and the miners are about at the limit of their resources.

Railroad tonnage is light. Strip mines show increased tonnages. All mines have "no bills" of all kinds, excepting lump, on track. The off-grade coals around Marion are having a hard time and are being marketed through a group of scalpers in Chicago.

In the East Jackson and Duquoin field conditions are bad with no immediate prospect of improvement. In the Mt. Olive district the railroad tonnage is about the only thing that keeps the mines in operation. Mines are getting 2 days a week, at most. In the Standard district conditions are unusually bad. Coal is still selling below cost and all sizes remain on track unbilled.

There is now a little activity in St. Louis in Southern Illinois high-grade coals. Other than that the movement is

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1921
	Aug. 30	Aug. 25	Aug. 18	Sept. 1
Index	164	165	165	204
Weighted average price	\$1.99	\$2.00	\$2.00	\$2.47

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

light, although there are indications here and there of increased buying which will mature early this month. Anthracite, smokeless and coke are slow.

**Kentucky Prices Advance**

It is reported that the operators down in the Harlan, Straight Creek and Jellico producing districts have booked a considerable number of orders of late, principally on movement to the South and Southeast, resulting in their having enough business in hand to be able to refuse orders unless prices are satisfactory, with the result that they are now pricing block coal for late September delivery at from \$2.75@ \$3 a ton, but still taking some immediate business at around \$2.50. Lump coal also has advanced a little in that section and is being priced as high as \$2.50, with egg as high as \$2.25.

There has been considerable improvement in general demand in the Southeastern field. However, it is claimed that the Southern demand will be filled soon and that prices probably will not go much over a peak of \$2.75 for the time being.

**Northwest Anthracite More Active**

Coal is generally dull at Duluth this week in bituminous, but anthracite has taken a decided spurt and out of town orders especially are good from the Dakotas and from Winnipeg. In fact the situation in Winnipeg seems to be bordering on the serious. Dealers there are worrying a little about prospective difficulties in getting enough coal. Shipments to this port have been steadily dropping off for the past three weeks, and this week only 37 cargoes arrived, of which six were hard coal. Fourteen are reported on the way, of which six are hard. So far this year, since

the opening of navigation, 510 cargoes have been landed, of which 414 were soft coal. This is below average, but the stocks on docks at the beginning of the period make up for the lack of shipments.

Soft-coal prices are the same. Hard coal is weakening a little, and the 10c. advance scheduled for the first of the month will apply only to stove, egg and nut. Prices are as follows at present with pea and buckwheat off: Stove, \$13.50; egg, \$13.10; nut, \$13.35; pea, \$10.60; buckwheat, \$8.

At the Twin Cities there is a noticeable shortage of steam sizes, but buyers with a little coal on hand are holding off. This moves the trade to hope that when cold weather arrives and coal demand picks up, there may be real strength in the Minneapolis steam market. The retail trade around southern Minnesota is now putting in hard coal. The volume on the docks is expected to be smaller this year than normal but movement inland can be swift during the next few weeks, due to heavy traffic in empties on their way back from delivering grain eastward. The 10c. increase Sept. 1 put hard-coal prices on a winter basis. There are no changes in soft-coal prices in spite of the lack of demand for those grades.

**West Improves Steadily**

Continued though slight improvement in the Southwestern market is reported, and operators are expecting an early opening of the heavy autumn demand. Farm prosperity is expected to be reflected in increased orders for domestic grades. No changes have been made in prices in the Kansas City district.

A marked stimulation was noted last week both in the sales and production of domestic coal in Colorado. Orders are beginning to come in more steadily now and operators are anticipating a busy month for September. The average working time of the mines picked up to twenty-one hours last week. Prices were unchanged to Sept. 1 although a slight advance was expected then.

In Utah intermediate sizes are a drug on the market, in spite of recent price adjustments. The sales office of one big firm reports business generally a little slower than a year ago. The demand for coal from the coast is very light now that the storage orders have been filled, while the Northwest business has not started yet, it is stated. Mining, smelting, cement and sugar industries are buying some coal. The sugar factories will start operations the first week in October. Retail business is in good shape.

**Better Domestic Market at Cincinnati**

Betterment of the domestic market with wider breadth of inquiry is the only bright spot in the sluggish situation at Cincinnati. Selling agents for coals of quality profess to have experienced little difficulty in getting the advance placed on prepared sizes. Lake buyers are beginning to evince interest in the market and some attractive buying orders for run of mine and 2-in. sizes have been placed lately. Low grades are hard to move, being the only lines on which forced concessions are being made. Smokeless prices for September are practically the same as for August, standard Pocahontas being held at \$4 by companies with bookings for the month, others taking only contract business at \$3.75. Some New River spot can still be picked up at \$3.50. The market on screenings still drags.

The domestic trade continues to be the best feature of the Columbus market, but even that lacks real vim. Buying by dealers is better but not equal to previous years. Smokeless and splints are moving best, although there is a fair business in Hocking, Jackson and Pomeroy lump. Dullness characterizes the steam trade. Buying is limited to present needs and many of the larger consumers are still using reserves, which in some instances are still heavy. Bargain buying is the rule, although there is not as much demurrage coal on the market as formerly. Utilities, railroads, schools and public institutions are taking a fair tonnage.

The Cleveland market shows better tone, due to the usual seasonal pick-up and improved business conditions. Output in eastern Ohio during the week ended Aug. 23, 296,000 tons, was the largest of any week since that of March 22, the gain over the preceding week being 49,000 tons. Spot prices remain pretty much the same except that slack has receded further to \$1.05@ \$1.10 for slack and \$1.10@ \$1.20 for nut and slack. The railroads in report increases in general traffic handled during the past few weeks.

### Further Gain at Pittsburgh

General line trade at Pittsburgh worked up a trifle farther in the past week. Little change has been observable from week to week, but there has been a decided gain in the aggregate in the past two months. There has been little increase in the volume of coal moving through the spot market, but there is a little more activity. Buying of domestic coal by retailers has been picking up, though it is not yet really active by ordinary comparisons. Prices are a little steadier.

The demand at Buffalo continues light, though some in the trade profess to see the fall trade coming into sight. The decision of the City School Board to use soft coal instead of hard for a great part of its fires will set many private users to asking for the same thing, as it means an expense of less than \$6 a ton in place of \$13 for anthracite. The coke trade is still inactive.

The Toronto market shows practically no change, as industrial requirements are still quite limited. A gradual improvement, however, is regarded as probable in view of favorable reports of the Western harvest, which will stimulate all lines of business. Quotations f.o.b. cars at destination are as follows: Steam lump, \$6@6.40; Pennsylvania smokeless, \$5.30@6.25; slack, about \$5.

### Inquiry More Active in New England

High-grade New River and Pocahontas has reacted from a low of \$5.25 per gross ton on cars Boston to \$5.35. Receipts at Mystic Wharf have been much lighter the past week and inquiry has been a bit more active, in some instances involving shipments through the balance of the year, some at \$5.75 gross ton on cars Boston for strictly pool 1 mine-run coal.

Due to rather heavy arrivals prices declined early in the week at Providence and as low as \$5.30 on cars was taken for what was claimed to be pool 1 coal. The situation has firmed somewhat since, so that \$5.40 is now the general asking price.

Quotations to local shippers for spot coal at the southern loading ports indicate complete maintenance of last week's levels, \$4.10 gross ton f.o.b. Hampton Roads being the lowest at which strictly pool 1 mine-run coal is offered.

There is actually no all-rail market in New England now. Consequently prices are entirely nominal, although save for some tonnage from non-union mines on the B. & O. which is offered at lower prices—\$1.75 to \$2 for really good coal—prices seem to be just about as they have been for weeks.

### Atlantic Markets Dull but Hopeful

Actual buying during the week at New York showed no real betterment, but there were more inquiries and taken as a whole the outlook is brighter. Favorable reports have been received as to business conditions in various parts of the East and sellers are optimistic that new orders will soon show themselves. The fact that the grain movement is expected to be in full swing soon has aroused some large consumers to the thought that they had better get busy and make arrangements for replenishing their reserve stocks, which are fast nearing depletion.

Orders have failed to flow readily as yet at Philadelphia, though more small orders are coming along. Railroads are taking a little extra tonnage, but the best customers are cement and brick plants.

The coal business at Baltimore is at the lowest ebb of many months as to prices. There is hardly a gas or steam

coal on the local market that is not selling at a mine-basis price below the actual cost of production. Not much coal is moving, however, at any price. The export situation has gone flat along with the balance of the trade. Only two shipments have been made on foreign account since Aug. 11.

Buying at Birmingham continues in restricted volume, but some increase in inquiry and business booked is reported and the trade is more hopeful. Orders are confirmed for the most part to small tonnages, but are larger in the aggregate with some contracts being made. Some improvement in the export and bunker movement is looked for, the demand being rather quiet at present.

### Anthracite Reflects Better Feeling

A better feeling pervades the hard-coal market at New York. Dealers, apparently desirous of taking advantage of the August prices for domestic sizes, ordered a little more freely last week. The greatest strength is in the demand of stove coal, which has moved easily all summer, but chestnut improved greatly. Egg and pea coals also were in better demand. Average independent quotations were firmer and with the supply tighter, due to the better demand and continued low production, tended to still higher levels. Buckwheat No. 1 is in better demand and the better grades are a trifle stronger in price. Rice and barley are moving better.

The Philadelphia market has not lost ground, although some are apprehensive that the recent stir was only a flash. The larger companies still continue to work a short week, but better working time is general among the independents. Stove is the most wanted size, and dealers are able to get it without much trouble. It is taken for granted that all shippers will increase mine prices as of Sept. 1. Steam sizes have brightened up a bit, with the exception of rice, which is still weak.

A seasonal increase is developing at Baltimore. Consumers apparently have been taking advantage of the last chance for summer rates, but a large number are not laying in the usual full winter supply. Wholesalers' price advances will force up retail prices at least 25c. per ton during September.

Trade at Buffalo is doing a little better and in a week or two ought to be up to something like normal proportions. People have been slow to buy. They have heard so much of the effort to get coal at lower prices that it has been hard to interest them.

Connellsville coke operators have advanced the price 25c. on fourth-quarter furnace coke contracts, two contracts at least being closed at \$3.25. A few operators are holding off in hope of securing somewhat more than \$3.25. By the reduction of last June most of the operators are paying the Nov. 10, 1917, scale, about one-third below the Frick scale of Aug. 23, 1922, which the Steel Corporation continues to pay. The spot furnace-coke market has advanced 10c. to \$3.10. Heating or medium sulphur coke has stiffened sharply and is now quotable rather steady at \$2.90@3. Foundry coke has been particularly dull in the past fortnight, but prices are unaltered, the market being quotable at \$4@4.50.

Foreign Market  
And Export News

British Coal Market Steady but Slow;  
Output Advances Sharply

The Welsh coal market is steady and has maintained its recent improvement, though the general situation is far from satisfactory. Some of the best coals are fairly well booked for prompt loading. Most of the Welsh operators are losing money at the current prices, though experience varies from colliery to colliery; some of the more modern pits are showing a profit, but the older concerns are undoubtedly losing heavily. Despite the fact that few collieries are able to cover operating expenses, they are reluctant to make concessions.

The men everywhere are anxious to keep the pits going, offering in some instances to work on a piece-work basis to prevent shutdown. In one case a mine employing 1,700 men has been restarted on these terms. The August wages of the miners have remained at the minimum of 42.22 per cent above the 1915 standard, of which the owners have to make up 18.17 per cent.

The Newcastle market has remained fairly steady since its improvement a week ago, and best steams and best gas coals have been able to find quite a ready market, though business in the other sections is slow. There are various contracts to be filled, of around 10,000-12,000 tons of gas coals for various European plants.

Production recovered sharply following the bank holidays, a cable to *Coal Age* states, output of the British collieries during the week ended Aug. 16 totaling 5,193,000 tons, according to the official reports. This compares with 3,446,000 tons during the week ended Aug. 9 and 5,010,000 tons during that ended Aug. 2.

The output during the second quarter of 1924 was 5,367,800 tons less than during the first quarter and 2,901,900 below the second quarter of 1923. There were 4,600 more wage earners during the second quarter than in the preceding one and 33,800 more than a year ago. The number of working days

was 8½ per cent below the first quarter and 6 per cent below the corresponding quarter last year. Exports during the second quarter were 280,843 tons less than during the first three months and 5,689,372 tons under those during the second quarter of 1923. Price reductions have been made since March of 4s. on foreign shipments and locomotive coal, and 3s. on household grades.

Hampton Roads Market Dull  
And Unpromising

Business at Hampton Roads is featureless, little activity being in evidence. Prices have fallen to a low ebb, threatening to break the low record since the war. Coastwise trade is dull, foreign trade almost invisible, and bunker business only fair.

Some increase in domestic trade is apparent, retailers placing orders for September shipment, somewhat strengthening the domestic price of smokeless coal. This business, however, has made no impression on the port trade. The supplies at tidewater are fair, shippers making every effort to keep things moving to avoid demurrage. The tone of the market is weak and little hope of early improvement is felt.

French Household Coal Steady;  
Industrial Inquiry Slow

The French coal market continues without important change. House coals remain steady, dry and half-bituminous fuels being in good request and disposals insufficient to meet the demand. For industrial coals, although the collieries are assured of a certain regularity in marketing by contracts, the inquiry is somewhat slower, due to the pessimism following recent political developments. The placing of dry smalls is rather difficult.

On the German side, liberal offers continue, outside of indemnity deliv-

eries, and this may be the prelude to further competition.

The freight rate is 20 fr. Bethune-Paris and Bethune-Reims.

Indemnity deliveries to France and Luxemburg for the first thirteen days of the month were 179,800 tons of coal, 173,200 tons of coke and 8,000 tons of lignite briquets, or 361,000 tons in all.

Supplies of coke to the O. R. C. A. for the first eighteen days of August were 165,207 tons, or a daily average of about 9,235 tons.

There is an accumulation of stocks at the Belgian mines and everywhere the situation is critical, especially in the district of Borinage, where the collieries meet keen competition in bituminous coals from British, French and even German mines.

Germany delivered 2,000,000 tons of coal to Italy on reparation account during the first six months of this year, according to official statistics at Rome.

## News Items From Field and Trade

### ALABAMA

A large tract of land lying between the furnace and coking plants of the Woodward Iron Co. and the pipe plant, at Bessemer, has been acquired by the Woodward company. It is understood that the property was purchased as a protection against encroachment, the rumor of the contemplated erection of a steel plant being denied by the officials.

Alabama produced a total of 4,689,641 net tons of coke during the calendar year 1923, according to the official report of State Mine Inspector C. H. Nesbitt, of which 4,448,128 tons, or 94.8 per cent, was made in byproduct ovens, and 241,513 tons, or only 5.2 per cent, was produced in the old beehive ovens. Byproduct ovens in operation during 1923 numbered 1,196.

The Alabama By-Products Corporation will begin immediately the construction of twenty-five additional ovens at its Boyles plant, according to official announcement. The corporation now has seventy-five Koppers ovens in operation and the necessary plant equipment to take care of the coke byproducts, and the additional ovens will provide for coking something like 40,500 tons per month, the plant addition to cost around \$1,000,000. While most of the coal coked at the plant at present comes from the Majestic and Imperial mines of the Bush interests in upper Jefferson County, some coal is coked for outside parties. Byproduct gas is furnished to a number of industrial plants in the district. The new unit probably will be of the Koppers type, it is stated.

### COLORADO

A total of 616,186 tons of coal was mined in Colorado during July, bringing the production for the state this year to 5,581,066 tons, according to James Dalrymple, state coal mine inspector. The average number of men employed in and about the mines since the first of the year is 12,317 and the average number of days worked in each mine, 99.2. Las Animas County led in the production of coal for July, Mr. Dalrymple said. In this county 272,510 tons were mined last month, making the total there for the year 1,902,739 tons of coal.

The state law governing the operation of coal mines was not complied with in the Alamo mine of the Alamo Coal Co., near Walsenburg, according to a report submitted to Governor Sweet by James Dalrymple, state coal mine inspector. The report was submitted in connection with an investi-

gation of the explosion on Aug. 5, in which Alex McBirnie, fireboss of the mine, lost his life and four other miners had a narrow escape from death or serious injury. In both sides of the mine many unlawful and dangerous shots were found," Dalrymple's report states. "Some of these shots were dependent upon others. The explosion appears to have been caused by the spitting of the fuse of one shot, which ignited the gas in the mine. It is evident the deceased did not examine the mine for gas before tamping, as required by law. The first south entry of the mine was advanced 156 ft. ahead of the air current, or 96 ft. farther than the law allows, all of which indicates that supervision in the mine was lax."

### ILLINOIS

The Wenona Coal Co., Wenona, has been closed and the mining property will be dismantled.

The Black Star Coal Co., whose mine at Logan has been idle since last April, resumed mining Sept. 1, employing about 500 men.

The Ellisville Coal Mining Co., Ellisville, with main offices in Galesburg, has resumed operations at its principal mine, with two hundred men employed. The Cripple Creek mine of this company is operating about half time.

The Bohemian Coal Co., 332 South Michigan Avenue, Chicago, has been incorporated with capital of \$40,000 to deal in and mine coal. The incorporators are M. J. Cherry, Edward F. Morgan and Robert J. Byrne.

Mine No. 9, of the Consolidated Coal Co., Murphysboro, which was one of the largest in the state twenty years ago, will soon be a memory, as orders have been given to dismantle the property. The mine was originally planned to employ 600 men. Until recently about 200 have been at work. The Big Muddy River broke into the mine in 1921, flooding it, but was later pumped out. Trouble with water and quicksand is believed to be the cause for the decision to cease operations in the mine.

### INDIANA

The Sunlight Coal Co., Indianapolis, has increased its capital stock from \$150,000 to \$750,000.

The Tunnelton Freeport Coal Co., at Blaster, will begin operation soon, it was announced by an official of the company last week. The mine is in

pool 11, and the holdings contain nearly half a million tons of that variety. It is equipped with the very latest methods of mining and shipping. The main office is in Tunnelton.

### IOWA

A vein of coal twenty-three inches thick has been reached in the new Thomas mine near Guthrie Center, at a depth of 94 ft. The mine was started in April and will be producing this fall.

Larger mines of the state have prepared exhibits for the State Fair at Des Moines. L. E. Stamm, secretary of the state mine inspector's department, is in charge. Mr. Stamm reports that in 1923 6,000,000 tons of coal was mined in Iowa. In 1917 the total was 9,000,000 tons.

### KENTUCKY

Southland Coal Mine No. 1, Henderson, opened Aug. 20 after being closed since April 15. Only thirty men could be used, because the mine will work only one section for the present. Officials say that all the men needed are available at the wages offered. All mines in Henderson County—fifteen—are operating at present, half of them on short time, two or three days a week.

Governor William J. Fields recently appointed assistant mine inspectors for the eight districts of the state as follows: James M. Boettger, DeKoven. First District; John Cates, Second District; John F. Brown, Ashland. Third District; James Dixon, Pineville. Fourth District; H. F. Reed, Central City, Fifth District; Burgess Thompson, Jenkins, Sixth District; G. W. Rose, Prestonburg, Seventh District, and D. W. Logan, Pineville, Eighth District.

Fire of undetermined origin destroyed \$30,000 worth of property of the Empire Coal Co. at Empire, Christian County, Aug. 17. The blaze had gained such headway when discovered that in spite of the hard work of the miners and citizens generally none of the buildings could be saved and practically all the contents were destroyed, the most valuable being the electrical apparatus, which was a complete wreck. The power house, boiler room, tippie and blacksmith shop, all frame structures, were burned, and sparks set fire to the headframe. Work has been temporarily suspended but in a limited way can be resumed in about a week. The fire will throw sixty-five men out of work for the time being. In normal periods the company employs 125 men.

Courtesy U. S. Distributing Corp.

### Houses for Miners in the Village of Dietz

If this is a "camp" the word has become synonymous in Wyoming with comfort. Well fenced, green with verdure, and provided with large porches, conditions are favorable, though nature contributes little but bright skies and fair—too fair—weather.

## MISSOURI

Fire of undetermined origin destroyed the buildings of the W. H. Fewell coal mine, near Sedalia, on the night of Aug. 16. The property loss was \$12,000.

The purchase of \$111,500 worth of coal land in Henry County by the West Missouri Power Co., of Pleasant Hill, has been approved by the State Public Service Commission. The commission likewise approved the purchase by the Pleasant Hill company of the assets of the Fort Scott & Nevada Light, Heat, Water & Power Co., for \$645,000 for the purpose of consolidation, and authorized issues of \$220,500 in 7 per cent cumulative preferred stock and \$870,000 in 20-year 6½ per cent first mortgage bonds. The company purposes supplying fuel to its various power plants from the Henry County coal deposit.

## NEW YORK

The city school board of Buffalo has awarded the contract for furnishing 26,000 tons of smokeless coal for school purposes to the Weaver Coal Co., of Buffalo, on its bid of \$5.74 for mine run, delivered. The coal comes from Cambria Co., Pennsylvania, and is said to be similar to Pocahontas. The coal will be handled through the city trestles of Spaulding & Spaulding. It replaces anthracite.

## OHIO

The Dillon No. 6 mine of the Wheeling & Lake Erie Coal Co., Lafferty, has resumed operations, giving employment to 250 men. The resumption follows a change from slope to shaft mining.

Common Pleas Judge Sowers has named Alfred A. Taylor receiver for the Ohio Service Coal Co., a Columbus corporation, upon petition of William H. Young, one of the three trustees named by the court to settle the affairs of the company. The dissolution of the

company has been authorized by the stockholders. Mr. Young says that he has paid debts of the company in excess of \$20,000.

The Black Diamond Mines, located near Amesville, are being cleaned up preparatory to placing them in operation after an idleness of several months. In all about 100 men will be given employment.

H. H. Heiner, formerly president of the Maynard Coal Co., of Columbus, and a well-known producer, recently was operated on for appendicitis at a Columbus hospital. He is now on a fair road to recovery.

## PENNSYLVANIA

It is reported on good authority that the H. C. Frick Coke Co. expects to start operations soon at two of its idle mines in the New Salem district between Uniontown and Brownsville.

Operations of the Pennsylvania Coal & Coke Co. in July resulted in a deficit of \$47,000. This compares with a surplus of \$51,000 in July, 1923. In the first seven months of 1924 the loss was \$188,000 against a surplus of \$634,000 in the first seven months of 1923.

Residents of Aristes have formed a forest-fire company to be known as Anthracite Forest Fire Co. No. 2, of Aristes, which is the second of its kind in the country, Mt. Carmel having the first. The new company has received permission from the Lehigh Valley Coal Co. to occupy its ground and will create a community playground.

Details have just been completed at Pittsburgh for the purchase of approximately 2,200 acres of coal land in Wayne township, Greene County. The deal involves \$605,000 and makes the transaction the largest coal-land sale of the year in Pennsylvania. The deal was made through an official of the Mellon National Bank, acting, it is understood, for the Koppers company, a Mellon corporation. No

immediate operation of the tract is anticipated, the purchase being regarded as an investment to increase the Koppers company fuel reserves. This corporation already has large coal holdings in West Virginia and this latest Greene County purchase adjoins the northern limits of the southern field.

S. D. Dimmick and H. M. Warren, general manager and consulting electrical engineer respectively of the Glen Alden Coal Co., are making a visit to England, France, Belgium and Germany, including perhaps the Upper Silesian field. They will return about Sept. 15.

The Lehigh & Wilkes-Barre Coal Co. has started extensive repairs to its breaker at No. 4, Audenried, and when the improvements are completed the No. 5 breaker at Honey Brook will be abandoned. It is planned to handle the coal hauled from Green Mountain at the No. 4 plant. There was not sufficient coal to operate the two breakers.

The Bethel Coal Mining Co., operating Bethel No. 1, at Twin Rocks, near Ebensburg, has resumed operations. William C. Shiffer, of Ebensburg, who has been active in the development of the mining interests in Cambria County, is giving the Bethel mine his personal supervision. The company has signed a contract with the Producers' Coal & Coke Co., of Johnstown, to distribute the output of the mine.

Seward E. Button, president of the Beaver Coal Co. and former chief of the state Department of Mines, announces that he is about to build a new breaker at the mine, which is located near Mountain Grove, to replace the one that was destroyed during the labor outbreak last fall. The contract is already let. The breaker will handle 600 tons or more a day and will be finished Nov. 15.

Refusing to obey an order of the executive board of the United Mine Workers to return to work, miners employed in the Henrietta slope of the Henrietta Coal Mining Co., at Dunlo, Cambria County, who went on a strike on Aug. 16, are still out. A decision to remain out was reached at a meeting of the miners on Sunday, Aug. 24. The miners are attempting to force the company's coal inspector to join the union. Rule No. 29 of the scale agreement exempts coal inspectors and mine foremen from membership in the union.

Plans for reopening the old Neilson colliery workings, located at the southwestern limits of Shamokin borough, reached a definite stage last week when a force of carpenters began placing the shaft head in condition. The abandoned Neilson properties were recently purchased from the J. Langdon estate by the Shamokin Coal Co., a newly organized mining corporation which has just completed the floating of the major portion of a \$1,500,000 bond issue through New York security houses. The present breaker building, which was erected by the old Carbon Creek Coal Co. and subsequently sold under the sheriff's hammer, is to be repaired and will be used temporarily by

the new concern in the preparation of coal. Eventually, however, a large steel breaker is to be erected, it is said. It is reported that officials of the Lehigh Valley Coal Co. are interested in the new mining project and that the Neilson workings may be used ultimately in tapping the rich coal basin owned by the Lehigh company in the Edgewood Park section of Shamokin.

S. E. Van Horn, superintendent of the Olyphant and Eddy Creek collieries of the Hudson Coal Co. for the past fifteen years severed his connections with that company last week. The cause of Mr. Van Horn's leaving was not announced by the company. Mr. Van Horn was at one time assistant to the chief mining engineer of the Hudson company and is widely known in the entire anthracite region.

The Sharon Coke Co. has requested a federal permit to erect a new break-water crib and a new mooring crib at its mines on the right bank of the Monongahela River, four miles below Grays Landing.

Announcement by the Lehigh Valley Coal Co. of indefinite suspension of operations at the Centralia colliery comes as a severe blow to the populace of that enterprising town. A total of 1,500 men were thrown idle with the closing of the colliery. It is the purpose of the company to completely remodel the old breaker, supplanting it with a more modern structure. The work, it is estimated, will require fully four months.

Another mine in the Uniontown district resumed operation last week when Superintendent J. L. Keck, of the South Union mine of the Jamison interests, sent his first shift of diggers into the pit since the shutdown several months ago. Repairs were engaged in getting the mine in shape for a week. This was easily accomplished as everything in the mine is less than two years old and in first class condition. During the period of temporary idleness the men have never left the company houses and practically all of the old men will be given employment at once.

The dispute regarding the duties of an engineer at the Cranberry colliery, of the Lehigh Coal & Navigation Co., which resulted in a strike of all employees at the operation following the discharge of the engineer, has been placed in the hands of Joseph J. Walsh, chief of the State Department of Mines. The strike has been in effect several weeks.

## UTAH

Utah coal operators mined 364,948 tons during July compared with 355,466 during the same month last year. The figures for July, 1922, were 374,934 and in 1921 278,092.

The Martin Coal Co., of Salt Lake City, has received a contract for 7,700 tons of coal, mixed sizes, to be delivered to the city schools. The price was \$32,985.

The Great Western Coal Mines Co. has received permission from the State Securities Commission to sell 60,000 \$10 shares of preferred stock with a

bonus of ten shares of common stock for each share.

## WASHINGTON, D. C.

Receipts of the federal government from bonuses, royalties, and rentals under the law providing for the leasing of mineral rights on the public domain aggregated \$13,627,588 for the fiscal year ending June 30, 1924, according to the Interior Department. The largest receipts were obtained from leasing mineral lands in Wyoming, the amount being \$12,270,322. The second state in the size of receipts was California, with \$957,480. Receipts from other states follow: Montana, \$221,426; Alabama, \$85,460; Utah, \$35,402; Colorado, \$33,513; North Dakota, \$10,587; Washington, \$6,280; New Mexico, \$4,784; Louisiana, \$2,295; South Dakota, \$34.

The U. S. Civil Service Commission announces an open competitive examination for Junior Engineer, to be held throughout the country on Oct. 8, to fill vacancies in the Bureau of Standards, Bureau of Mines, Bureau of Chemistry, and various other branches of the government service, at an entrance salary of \$1,860 a year. Advancement in pay may be made without change in assignment up to \$2,400 a year. For appointment outside of Washington, D. C., it is probable that this same rate of pay will be applicable, but if not, the entrance salary will be from \$1,500 to \$2,000 a year. Full information and application blanks may be obtained from the U. S. Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. civil-service examiners at the post office or custom house in any city.

## WEST VIRGINIA

The Jones & Laughlin Steel Co. is reported to have completed preparations for the opening and development of 15,000 acres of coal lands along the Monongahela River, near Dunkard. Operations are expected to begin about Nov. 1.

A deed was filed at Clarksville, Aug. 23, in the office of Clair N. Parish, clerk of the county court, transferring to the Allied Coal Co. a complete mining plant and 79.56 acres of coal in Clay district, Harrison County. The deed includes the mining rights together with all the mining equipment located on the premises and specifically states that the transaction is a sale in gross and not by the acre. Chester S. Shinn, C. H. Tarleton, Mary C. Tarleton, L. A. Riggs, Tusca Morris, Harriet B. Morris, Harry B. Crane, Edna D. Crane, Boyd S. Fleming and Eva B. Fleming, all of Fairmont, are the makers of the deed.

## WYOMING

The Union Pacific Coal Co. has ordered a shale dust pulverizing plant from the Williams Patent Pulverizer and Crusher Co. of St. Louis. The plant will pulverize from two to three tons of shale an hour to a texture which will admit of a minimum of ninety per cent of the dust passing through a 200-mesh screen. The plant

is expected to be in operation at Rock Springs before Oct. 1.

## CANADA

A meeting of the former employees of the Morden mine, at Nanaimo, was held Aug. 13 to consider the proposal of B. H. Brown and J. Arbuthnot, representatives of the West Coast Collieries, Ltd., that the men take stock in the company instead of the wages due to them, and thus enable the company to re-start work at the mine. The proposition was rejected and the Provincial Minister of Mines and Attorney General were advised of the decision.

A company has been formed to produce coke at St. John, N. B., the capital being largely from the United States. According to tests that have been made Minto coal has proven the most satisfactory. The intention is to build a plant at St. John, before the winter sets in.

The strike of miners in Alberta coal mines has caused a direct wage loss to the miners of something like \$2,500,000 in the four months, according to an estimate of John F. Stirling, chief inspector of mines for Alberta, based on the loss in coal production as compared with the same four months in 1923.

The Allan shaft will be reopened soon, according to representatives of the Dominion Coal Co. On June 30 an explosion occurred in this mine causing the loss of four lives. Following the explosion, a fire occurred which raged for about six weeks. An inspection of the mine recently by agents of the company in conjunction with representatives of the provincial government indicated that the fire had been extinguished by the company's fire fighters. T. J. Brown, Deputy Minister of Mines, has given his approval of the decision to reopen.

## Industrial Notes

The General Explosives Co., of Joplin, Mo., has been acquired by the DuPont Powder Co.

The Mine Safety Appliance Co., Pittsburgh, Pa., has entered into an agreement whereby that company becomes exclusive representative of the Bradley Pulverizer Co., Allentown, Pa., for the distribution of the latter's mills for pulverizing shale and limestone for rock-dusting purposes.

Important changes in the personnel and policies of the Bassick-Alemite Corporation and its subsidiaries are announced as a result of a recent meeting of the Board of Directors in New York. The Bassick-Alemite Corporation has purchased the Allyne-Zerk Co., which will be operated as an independent unit but under the same general management as the other units that make up the corporation. E. W. Bassick, of Bridgeport, Conn., as president of the corporation will take a more active part in the management of its affairs in the future. The general direction of the properties will be in the hands of an executive committee, headed by Mr. Bassick and including E. S. Evans, E. E. Allyne and James G. Alexander, vice-president of the Central Trust Co., Chicago. E. S. Evans, president of E. S. Evans & Co., a subsidiary, becomes vice-president of the Bassick-Alemite Corporation in charge of sales of all units of the corporation, including the Bassick Manufacturing Co., of Chicago, manufacturers of the Alemite High Pressure lubricating system, and the Allyne-Zerk Co., manufacturers of the Allyne-Zerk lubricating system.

## Traffic News

### Railroads to Fight Interstate Rate Cut to East St. Louis

Counsel for the thirteen railroads serving the inner group of coal mines adjacent to East St. Louis, Ill., have announced that an appeal will be taken from the recent decision of Circuit Judge George A. Crow, of Belleville, Ill., who on Aug. 15 declined to stay the order of the Illinois Commerce Commission reducing the intrastate freight rate on coal shipments to East St. Louis. Under the Illinois commission's ruling the rate on mines within 30 miles of East St. Louis was cut from 91c. to 70c. per ton while the rate on other miles of the inner group was reduced from 91c. to 80c. The case will go to the Illinois Supreme Court.

### Protests Coke Rates to Mobile

The Chamber of Commerce of Mobile, through its traffic department, has filed protest against the recently published rates on coke from points in Tennessee and Georgia to Mobile for export movement, alleging that such rates are unjustly discriminatory against Mobile and preferential to South Atlantic coast points, and asking a suspension of the tariff which was to have become effective Aug. 28.

### South Dakota Cuts Rates

The State Railroad Commission of South Dakota announces a general reduction of freight rates on steam coal to numerous points in that state, at the same time that rates from South Dakota to southern Minnesota points are increased under the ruling of the Interstate Commerce Commission. The change is effective Sept. 10 and affects many points in South Dakota. Watertown gets a reduction from \$4.32 to \$3.92; Huron from \$4.74 to \$4.31; Miller from \$5.10 for both steam and lump to \$4.95 on lump and \$4.51 on steam; Mobridge from \$6.16 on all sizes to \$5.29 on lump and \$4.86 on steam. Numerous other towns get similar reductions. Railroads serving the Lake Superior docks have made cuts of 40c. to a number of South Dakota points.

## Association Activities

The Central West Virginia Coal Operators Association was formed by a group of operators with open-shop mines in the Harrison County field of West Virginia at a preliminary meeting held at the Waldo Hotel in Clarksburg, W. Va., J. M. Orr, H. G. Smith, T. R. Craig, James Dudley and J. P. Keeley were named as members of a committee to apply for a charter, which was granted on Saturday, Aug. 23. Daniel Howard presided over the meeting, T. R. Craig acting as secretary. Approximately 25 operators enrolled as members, representing about 60 per cent of the tonnage produced in the Harrison County field. A committee was appointed at the first meeting to draft a set of by-laws and there will be another meeting soon to elect directors and officers.

Fred S. McConnell, of Cleveland, vice-president of the Enos Coal Mining Co., was elected president of the Indiana Coal Producers' Association, at the annual meeting held recently in Indianapolis. Hugh B. Lee, of Terre Haute, general manager of the Maumee Collieries Co., was elected

vice-president, and Michael Scollard, also of Terre Haute, is secretary-treasurer. The executive board is composed of the following: J. T. Moorman, president and general manager, Patoka Coal Co., Indianapolis; Wick Dixon, general manager, Modern Fourth Vein Coal Co., Jasonville, Ind.; R. H. Sherwood, president, Sherwood Coal Co., Indianapolis.

## Trade Literature

**Static Condensers for Power-Factor Correction.** Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa. Circular 1670. Pp. 20; 8x11 in.; illustrated. Discusses need for power-factor correction and methods of obtaining high power factor. Analyzes method of selecting proper corrective device for power factor.

The Mesta Machine Co., Pittsburgh, Pa. has issued a four-page folder giving results of tests with its **Una-Flow Engines**. A short illustrated description of these engines is also included.

**Westinghouse Fabrics and Papers.** The Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa. Folder 4532-A. Pp. 23; 4x7 in. This booklet should prove useful to all users of insulating material.

**Okonite Installations.** The Okonite Co., Passaic, N. J. Pp. 32; 9x12 in. This finely illustrated booklet is composed of views showing railroad and power installations of Okonite wires and cables.

The Ridgway Dynamo & Engine Co., Ridgway, Pa., recently issued Bulletin No. 21, which supersedes Bulletin No. 28, describing its turbo generator units. The bulletin is well illustrated with photographs and line drawings, has 27 pp. and measures 8x10½ in.

**The Improved "Rochlitz" Automatic Water Still.** Weber Bros. Metal Works, 108 North Jefferson St., Chicago, Ill. Pp. 8; 5½x8½ in.; illustrated. A combined condenser, purifier and aerator for producing a pure and palatable water for drinking and manufacturing purposes.

## Obituary

**Bushrod M. Watts**, formerly president of the Baltimore Coal Exchange and one of the best known figures in the retail coal trade of the East, died in Baltimore, Aug. 27 as a result of an attack of pneumonia. Mr. Watts had not been in the best of health for some years.

**James LeRoy Cook**, prominently identified with the coal industry of Salt Lake City as a sales manager for several years, is dead, following an acute attack of rheumatism of the heart. Mr. Cook was at one time associated with the United States Fuel Co., but at the time of his death was sales manager for the Kinney Coal Co. He was only 35 years of age.

## Coming Meetings

**New York State Coal Merchants Association, Inc.**, 14th annual convention, Sept. 4-6, Stamford-in-the-Catskills, N. Y.; headquarters Churchill Hall. Executive secretary, G. W. F. Woodside, Arkay Building, Albany, N. Y.

**American Chemical Society.** Fall convention Sept. 8-11, 1924, at Ithaca, N. Y. Secretary, Gas and Fuel Section, O. O. Malleis, the Koppers Co., Pittsburgh, Pa.

**Oklahoma Coal Operators' Association.** Annual meeting Sept. 11, 1924, McAlester, Okla. Secretary, A. C. Casey, McAlester, Okla.

**Association of Iron and Steel Electrical Engineers.** Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Belt-Conveyor Carrier with Pressed-Steel Shell

Improvements to its belt-conveyor carriers have been announced by the Stearns Conveyor Co., of Cleveland. The pulley shell is made of pressed steel which, as compared with a cast-iron shell, has the advantages of lighter weight, greater strength, and better balance. The rounded edges prevent injury to the belt.

Antifriction bearings are used between the hardened steel shaft and the

### Cutaway Section of Carrier

The one-piece tube which forms the grease chamber is firmly held by the tapered ends of the pressed-steel shell.

one-piece tube which is held firmly in the tapered ends. Grease is forced by high pressure into the large chamber between the shaft and shell, and it is claimed that one filling is sufficient for a period of from six to twelve months. The design is such as to prevent dust from entering the bearings and to make it difficult for any foreign substances to accumulate on the outside of the pulley.

The advantages claimed are: Saving of power; increased life of belts and carriers; reduced costs of lubrication, inspection and maintenance; and more continuous service.

### Dump Car Operated by Steam From Locomotive

Recently an interesting type of automatic dump car was placed in service handling breaker refuse at the mines of the East Bear Ridge Colliery Co., Mahanoy Plane, Pa., in the anthracite region.

The side-door dump is operated by cylinders supplied with steam from the locomotive and is fully controlled by a single valve in the locomotive cab. If desired the dumping may be done while the car is in motion, the design being such that the material is deposited clear of the track.

This long type of dump car is of rugged steel construction and is designed with a low center of gravity. The car has a capacity of 20 tons and its overall dimensions are as follows: Length 16 ft., width 8 ft., height 7 ft. The bottom has a 45-deg. pitch and the track gage of this particular in-

**Locomotive Supplies Steam to Operate Dump**

The latching and unlatching as well as the opening and closing of the dump are controlled by one valve in the locomotive cab. The material is deposited several feet from the track.

stallation measures 36 in. Not only is provision made for braking by hand but a steam brake is provided which can be operated either independently, or in conjunction with the locomotive brake. All steam connections between

the car and locomotive are of flexible brass tubing, and the steam lines are cleared of water by automatic traps. The Bloomsburg Locomotive Works, of Bloomsburg, Pa., is the designer and builder of this car.

### Improved Grease Cup

A grease cup is a small item in a plant or factory, but it can be a nuisance and a cause of expense. Recognizing this, the Link-Belt Co., of Indianapolis, has developed a new top for their regular compression grease cup. This top is hexagonal in shape, which provides not only a good grip for the hand but also for a wrench. Cold, stiff grease makes a compression cup very hard to turn, and a pipe wrench is not always accessible. The hexagonal shape provides grip spaces for the ordinary wrench.

This cup is also provided with a raised slot so that it can be turned with a screwdriver, when it is so located that it is inconvenient for the hand or wrench.

### Loading Machine with Tread Similar to War Tank

A new portable loading device of the bucket type suitable for moving over soft, rough or uneven ground has been developed lately by the Jeffrey Manufacturing Co. This new machine, known as the Tanktred Loader, has an elevator boom designed along lines similar to the radial loader boom, but the three-wheel chassis is replaced by a tanktred crawler mounting, and the lower end of the boom is fitted with an effective clean-up device and scoop.

The loader has a capacity of  $1\frac{1}{2}$  to 2 cu.yd. per minute and will handle rough material. The framework of this member is built up of wood and steel to provide great strength and elasticity. Two strands of Hercules chain are used to carry the buckets. The latter are 18 in. long, of malleable iron, with high backs and renewable steel-digger edges. To receive the discharge from the elevator buckets, the top of the boom may be fitted with a swivel spout, to give as much as 11 ft. clearance from the ground. Or, in place of the swivel spout, a measuring, or batch hopper, with valve in the bottom, and having a capacity of about 21 cu.ft., may be substituted.

The tread proper consists of heavy steel plates, bolted to a chain made of cast-steel side bars, hardened steel knuckles and hardened steel pins. The

tread sprockets are heavy cast steel. The thrust from the under side of the tread is taken by chilled rollers, placed in proper position. The main weight of the machine is carried on these crawlers by a three-point suspension, to take care of rough and uneven ground.

The clean-up device consists of revolving spiders, having hardened-steel pin inserts and a plate-steel scoop. The heavy cast-iron spiders are brass-bushed and revolve on the extension of

the foot shaft to and through the scoop to the body of the machine. The steel-pin inserts are so placed as to loosen thoroughly compact material and carry it forward into the path of the buckets.

All the driving mechanism is mounted in a rigid steel and cast-iron, self-contained frame, which in turn is mounted on the framework proper of the machine. A heavy steel shelf supports the power unit so that all gears are in line and cannot get out of proper mesh. All gears are steel with cut teeth and the bearings are bronze-bushed and grease-oiled, which keeps out the dirt.

Operation is easily controlled by levers conveniently located and easily reached by a man standing on the platform which is attached to one of the tread frames. Each function of the machine is completely independent of the other. Propelling, steering and operation of the elevator are accomplished through multiple-disk clutches.

The treads are controlled by brake mechanism on the differential shaft making it possible to turn the machine on the center of either crawler as a pivot. The raising and lowering device is self-retained and automatically locks in any position. Provision is made for two speeds, both in the forward and reverse direction: The fast speed, 50 ft. per minute, for moving the machine from pile to pile, the slow speed, about 2 ft. per minute, for feeding into the material.

Lubrication, which is a vital factor in the life and efficient performance of any machine, is thoroughly and effectively taken care of by a high-pressure lubricating system, which embodies the much-favored explosive action. All bearings and moving parts are equipped with high-pressure fittings, so with the aid of a grease gun, all parts are quickly and easily lubricated.

This system, embodying the explosive action, not only forces the grease into otherwise inaccessible parts but forces out dirt and foreign substances.

**Loader for Traveling Over Rough or Soft Ground**

Control levers on the differential shaft are used to turn the machine either on the pivot wheel or the center of either crawler. High-pressure lubrication is applied to all bearings.

## Our Modern Proconsuls

ANCIENT ROME sent its proconsuls to rule over its conquered provinces. Gradually a system was established by these men which perpetuated their terms of office. They discovered some breach of discipline in those they ruled. This gave them a reason for invading their territories and for taking of their substance. Part of it they kept for themselves and part they used to provide pageants, gladiatorial and animal fights, races and bread for the people at home who, thus bribed, voted for their continuance in office. This form of graft was eminently successful and became eventually almost a fixed custom.

Our modern proconsuls, called politicians, do not rob foreigners but prey on their own people. They regularize their actions by false charges of violation of the laws. La Follette is a sample of such people. He has just announced that the coal men and railroads had combinations in restraint of trade and were robbing the farmer. They must be put under severe control so that the most numerous body in the electorate, the farmers, shall have cheaper coal and transportation. He made this statement despite the fact that bituminous coal was selling at a price below the cost of production in all the union mines and that mines were daily being closed either by the sheriff or voluntarily.

That is what is meant by bringing coal and the railroads into politics. It is a modern form of proconsular graft, only, as already stated, it is our own people and not foreigners who are victims of the political ambitions of these politicians who seek by false charges and the power of the state to create and perpetuate their tenure of office.

## "Be to Our Faults a Little Kind"

ON THE editorial desk lies a letter from an Englishman lately engaged, as he tells us, as superintendent in a mine in North America. He is having trouble in convincing his friends that the tales he has told about Orient, Zeigler and Lynch mines are not figments of a disordered imagination, and he wants some clippings from *Coal Age* to prove that his statements are justified. We remember receiving an inquiry for copies of the records made at Orient and Zeigler from an Australasian chief inspector. He was amazed at the hoisting performances described in our columns.

We say this of American mines not in pride but rather in defense. The coal industry in America has been generally condemned by those who do not know it, by its malicious, consistent, and unscrupulous enemies. They have declared it to be most deplorably inefficient. It should have some capable men, they say, enlisted in its improvement and development.

Every coal man in America knows that there are incapable coal men and inefficient coal mines in this country. That is not unnatural. There are village

smithies also, and there are big automobile plants. There are women knitting socks by hand, and there are big power-mills with many spindles. At the same time the average coal mine has an efficiency that averages well with other industrial operations, and some mines are noteworthy for their excellent management and the vastness of their activity. Coal mining is not perfected nor will it ever be perfect, but it is progressing, and these incredulous Englishmen are evidence that we have done something worth while.

When European engineers come over here they are disposed rather to wonder than to criticize. Nowhere in Europe are such tonnages produced per mine or per man. We do not have such elaborate plants and housing as France, Belgium, Germany, and probably Holland, but we are efficient. Yet that is the very quality which our skeptical fellow countrymen will not concede to us.

## Every One's Job Is Easier Than Ours

REMARKABLY easy is every man's job. We could do it much better than he can. We are like the man who had never handled a fiddle but supposed he could play it offhand if only one were given him.

All the world believes there is no trick about coal mining—except perhaps the art of excessive charging for coal. We are told on all hands that we are the veriest dubs at an ancient art. But do not be mistaken, ours is *some* job. If others took hold of it, they would find that out. By the way, some have tried it and have found out already. We will not mention names though a lot occur to us—men who have burned their fingers at it.

Railroading is a sizable job especially the work of Class I roads, those having an operating revenue of over \$1,000,000 a year. In the first quarter of this year they originated 8,016,439 car loads of which no less than 2,327,481 were of coal or coke. That is 29 per cent of the whole. Seeing that this has been an off year for coal and coke, more coal being consumed than was being mined, and that coal cars have a larger weight capacity than other cars, that is quite a large proportion. Let us inquire therefore as to weights carried. The total number of tons "originated" in that period was 276,352,426 tons; of this 115,413,844 tons were coal and coke. That is 41.7 per cent.

It is clear therefore that the coal companies that have to haul this coal to the railroads have quite a large job on their hands especially as the cars run from less than one ton to more than eight tons capacity and have to be hauled over roads which conditions do not permit to be graded satisfactorily. This transportation job is larger than coal men themselves realize and one that men outside the industry utterly fail to comprehend. Some of the coal is transported as much as five miles. Much, it is true, is not carried nearly so far. No one

knows how far the average distance is. A wild guess might place it at two miles. But whatever the distance the job is immense. Imagine transporting 40 per cent of the traffic of the Class I railroads and much of the other classes underground in small cars averaging perhaps one-thirtieth the size of those used by the railroads.

One reason for the ease with which coal is gathered and transported is the use of electricity. If the railroads had been as forehanded as the coal companies they would be performing their heavier haulage functions with greater economy and despatch and less annoyance to the public. But there again, we are operating the railroads! If only we could!

### Our Mine Shops

LARGE outputs, increasing use of machinery, long hauls and heavy cars are going to make mine shops increase in size and importance. They may become before long, wherever large companies concentrate the repair work of many operations as space-consuming and as imposing as the shops of some of the smaller Class I railroads.

The progress has been rapid. In the nineties a drill press, a forge, a bellows, an anvil, a few hammers, a quenching barrel, a paring knife, some spanners and wrenches, a hand grindstone, a box of taps and dies with hand pipe cutters, and a few carpenter's tools, not forgetting a two-man crosscut saw, together filled the need for tools at most bituminous mines. Today such mines have shops equipped with a lathe or two, a drill, pipe machine, hack saw, hammer, a bit shaper, grindstone and woodsaw all driven by power with perhaps a section serving as a foundry. In addition would be oxyacetylene and electric-welding equipment and conveniences for the winding and making of armatures—all these for one mine of moderate size. Ten years from now such equipment will be regarded as entirely inadequate. Steel cars, loading machinery, conveyors and perhaps steel props will make more and heavier equipment necessary.

### Part of a Larger Program

STABILIZATION of the coal business is dependent on a larger undertaking that proposes to iron out the fluctuations of all industry. If the railroad business, the steel, cement and automobile industries, construction and all other activities were not seasonal the coal business would be less irregular. Some uses for coal, however, are so seasonal that they will never be corrected till we use power in the summer to cool by tempered artificial ventilation our homes and our offices. Perhaps the day will come when industrial activity will be uniform and when power will make our buildings cool, but both hopes appear a long way off. Still publicity might introduce some such development as the latter, giving regulated, dry, cool, dustless air in place of uncertain, humid, hot and dirty drafts from windows or a disk fan which cause colds and sweep the papers off desks.

And strange to say in a trifling degree the desire to keep at least our refrigerators and our drinks cool intensifies the difficulties of the coal producer, for the retailers would be more anxious to sell coal, more active in urging it, and more ready to reduce the price if they were not busy peddling ice, and if they had their motive power free to distribute coal. The retailers by taking

on the sale of ice have been doing a little stabilizing of their own to the disadvantage of the coal industry.

Another source of irregularity is not due to an unequal need for coal but to an inequality of the ability to pay for it. When business is slack, industry and individuals lack money to buy coal and both wait as long as they can or dare before buying.

A long, long road lies ahead. In 1924 we find ourselves farther than in 1923 from the happy consummation, despite reports and advice galore. The only real cure is an economic and not an ethical or altruistic one. Give an equal demand the year long and suppress the business cycle, and the coal man's trouble is solved.

The consumer caused the irregularity and not the coal man. He will only cease to cause it when he wants coal the year round. Every movement of the government to save him, when he is short of coal, from the consequences of his folly makes him less frugal and weakens his dependence on himself. The coal industry that has to take the blame of all the consumer's faults sincerely hopes that he will reform because the coal man must ever accept vicarious punishment for the consumer's misdoings. Still there is little expectation that the consumer will be regenerated.

### International Courtesies

RECENTLY we were favored with a copy of a new publication entitled *The Colliery Engineer* published in London. It was a technical journal covering the coal industry. As *Coal Age* had purchased *The Colliery Engineer*, of Scranton, some years back, a paper with a long and honorable record, and had borne on the title page for years the legend "Coal Age with Which Is Consolidated The Colliery Engineer" we looked with some dismay on this new publication which tried apparently to obtain a glory that did not rightly belong to it.

The company which publishes this paper is also publisher of the "*Railway Engineer*" the "*Power Engineer*" and the "*Marine Engineer*," and it was only natural for it in entering the colliery engineering field to follow its former practice and add to its list of publications that of "*The Colliery Engineer*." An exchange of courteous correspondence, however, made the British publishing house decide that it would be an act of consideration to change its name to "*Colliery Engineering*" and in a letter dated Aug. 20 it inclosed an editorial of which we reprint the follow paragraph.

"It has been pointed out by the proprietors of our esteemed contemporary that they like to regard the whole of technical literature printed in the English language as a unity, whether the publication be in Great Britain, in one of the English-speaking British colonies or in the United States, and that consequently they believe that any duplication that leads to confusion is undesirable. With these sentiments we are in cordial agreement, and accordingly we have adopted the suggestion, so courteously made, that the title of this journal should in future be *Colliery Engineering* instead of that originally selected."

*Coal Age* wishes to thank *Colliery Engineering* on its kindly acceptance of the suggestion and anticipates for its contemporary the best of success, which, indeed, the character and appearance of its issues seem destined to assure it. In no other country than Great Britain, we believe, is a detestation of literary piracy in any of its many forms more heartily disapproved.

General View, Dudley Coal Co. Tipple

## Dudley Mine's Unusual Dump and Picking Methods

Revolving Dump Drops Coal to a Boom That Feeds a Steel-Tube or Storage Bin—Each Carload Passes Over Boom Alone and Consequently Every Man's Product Gets Individual Inspection

BY W. R. COLE

Mining Engineer, Kentucky River Coal Corporation,  
Hazard, Ky.

**A**T THE HEAD of Caudill Branch of Rockhouse Creek, a tributary of the North Fork of the Kentucky River, is located one of the best equipped coal operations in the Hazard field, that of the Dudley Coal Co.

In addition to 300 acres of No. 7 and 600 acres of No. 6 coal, this company also owns 2,325 acres of the No. 4 bed estimated to contain 16,000,000 tons. As the interval between the No. 4 and No. 6 measures at this mine is 330 ft. it was believed that it would not injure the upper bed to work the lower one first. Adequate equipment for operating the No. 4 bed could be installed for a smaller outlay than would have been necessary for the upper deposits. Furthermore, contrary to the conditions usually encountered, the No. 4 seam was here as thick as either of the upper beds and contained a better quality of coal.

The No. 4 bed is only 90 ft. above the railroad. As the hills are high in this vicinity, this measure contains a large area of coal lying in an unbroken body, not cut up by erosion like the coal beds at many operations in this field.

Openings into the coal were made on both sides of Caudill Branch. This stream, as shown by the accompanying map, extends about 3,000 ft. into the property. In order to provide for rapid development seven different openings were made, the coal produced being hauled around the hill to the tipple on outside tramroads. At present, however, the haulage has been concentrated inside the mine, loads being gathered to suitably located central points and brought out from the No. 1 mine opening on the east side of the branch and through the portal of the No. 4 mine on the west side.

Mining is conducted according to the panel system. On account of the erosion of Caudill Branch, it has not

as yet been possible to make all the panels of the same size either in length or width. When the outcrop stage of working has been passed, however, it is planned to make all panels 350 x 1,000 ft. with a 50-ft. pillar separating them. A 150-ft. barrier pillar will protect the entries.

### PILLAR WIDTHS COMMENSURATE WITH OVERBURDEN

Near the outcrop, rooms were turned on 50-ft. centers and driven 22 to 24 ft. wide. Since the workings have been extended well under the hill, however, the centers have been increased to 60 ft., leaving an average pillar about 37 ft. wide. This is thought to be adequate, as the average overburden is only about 400 ft. and at the maximum 900 ft. thick. Should conditions appear to warrant it, however, the pillar width will be increased still more.

Pillars are robbed to within 50 ft. of the entry. When the last rooms are finished, the entry stump, chain pillar and 50-ft. panel pillar are drawn back. These pillars are robbed by machine on the butt-off system. If the roof conditions are favorable, which is generally the case, even the 6-ft. stumps produced in drawing back the pillar are cut with the machine. If, however, the roof is weak, these stumps are taken out with the pick. So far the pillar work has been highly successful and the total recovery of coal, including an estimated 4 per cent loss in handling and preparation, is 92 per cent of the merchantable coal in the bed.

On all main aircourses, brattices are made of cut stone. This is quarried from the nearby hillsides and plastered with cement. Though this may seem rather extravagant at first blush, it must be remembered that from the outcrop the mine will extend 8,800 ft. to the rear and about 5,600 ft. on either side before another

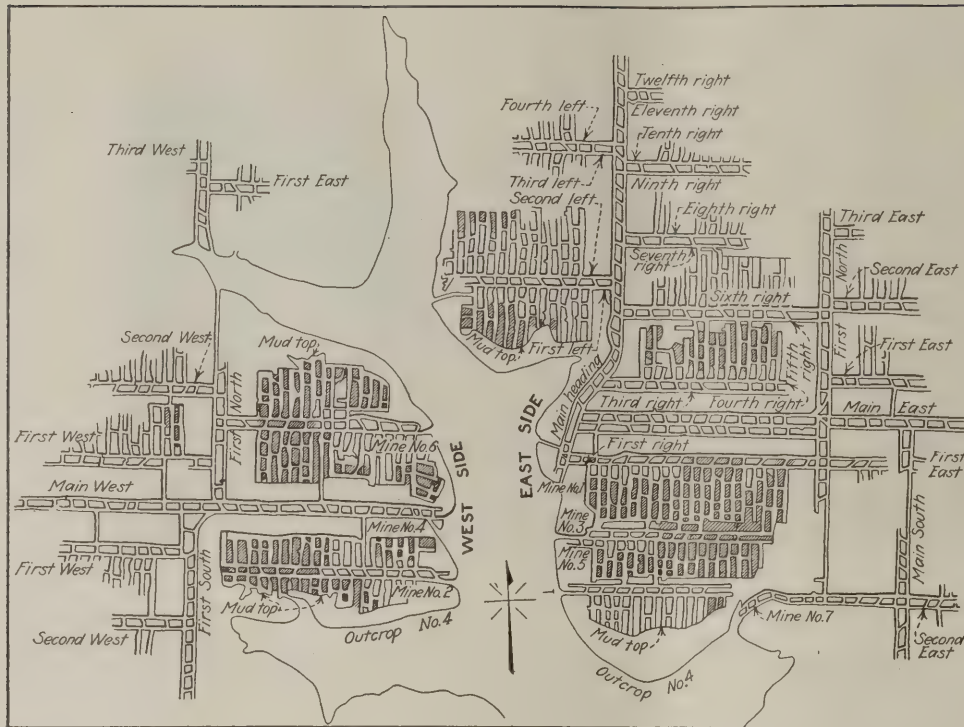

FIG. 1

### Map of Dudley Coal Co. Development

In order to attain an output quickly drifts were driven into the bed at various points along the outcrop, the coal being hauled to the tippie over surface tramways skirting the hill. After a number of headings and rooms had been driven, however, the loads were assembled at partings underground and hauled out from two openings one on either side of "the hollow."

opening can be made to daylight. This shows the economy of building tight stoppings.

Entries are driven 15 ft. wide and the track placed close to one rib with a 3-ft. walkway along the other side. This enables employees to go in and through the mine without traveling on the track, except at cross entries.

Forty-pound steel is used on all main haulroads and 25-lb. rails in the rooms. All switch points both in entries and rooms are provided with switch stands. These are of the upright type and are easily operated. Though they hold the switch points rigidly in place when set, it is only necessary to throw the lever off center for the weight of the ball to carry it the rest of the way.

The use of the upright switch in mines has been much criticised. This is because a man is likely to trip over it while working or to have such difficulty in throwing it that when resting his weight on the handle he may be thrown by its decreased resistance in front of the locomotive.

At the Dudley mine plenty of clearance is maintained between the rib and the rail. Ample space thus is afforded for the snapper. As demonstrated by the manager, the trip rider can travel ahead of his trip and readily throw the switches from an upright position. With the ground throw type, on the other hand, he must first stoop down and lift the switch lever up, and then throw it down on the other side. In either case, should the switch stick or give way suddenly, he

FIG. 2  
Room Face

Excellent roof conditions prevail in this mine, as may be judged from this picture. Note the band or parting of "jackrock" plainly visible in the coal at approximately the elevation of the hands of the man on the right. This is the only impurity found in this bed, and as it does not adhere to the coal, either above or below, it may be separated easily and gobbed. The upper bench of coal in this bed is quite uniform, variation in thickness being confined almost entirely to the bench below the parting.

Fig 3—Loads at No. 1 Driftmouth

Two things are noticeable in this picture—the blocky nature of the coal and the extreme length of the car-wheel hubs. The first is responsible for the large percentage of lump in the product shipped; the second affords a ready means of holding the car in the rotary dump when it is in the overturned position.

is likely to be thrown off his balance. Should this occur when he is in a forward-leaning position his head probably would be pushed across the rail in front of the car or locomotive, and should he slip or fall his whole body would be thrown directly in front of the trip. This very thing has occurred upon many occasions.

The No. 4, or Fireclay, bed yields an excellent all-purpose fuel. It is free-burning and practically clinkerless, low in sulphur, with a fusing point for its ash of 3,000 deg. F., or considerably above the maximum temperature attained in the average boiler furnace. Tests made with this coal in the metallurgical furnace have proved it to be clinkerless, the grate bars being left perfectly clean. It also has been proved by test to be an excellent gas and byproduct coal. A characteristic analysis of the bed is as in Table I.

Table I—Analysis No. 4 Bed, Dudley Mine

With all the different markets available, this company has made elaborate preparations to size its product carefully and to free it from refuse.

#### VARIATIONS IN THICKNESS IN LOWER BENCH

The bed varies in thickness from 40 in. to 6 ft., having an average thickness of about 56 in. A 3- to 4-in. band of flint clay, locally known as "jackrock," occurs from 6 to 24 in. from the bottom. It is characteristic of this measure in this vicinity to increase in thickness as the bottom dips, so that, though the bench above the parting is quite regularly about 42 in. thick, the thickness of the bench below the "jackrock" varies appreciably.

As this parting is too hard to be cut by a mining machine, the coal is mined below it and shot down in the usual manner. The upper bench is then loaded

off the parting, which does not adhere to the coal either above or below. The "jackrock" itself is then taken up, loaded out in the entries or gobbled in the rooms, leaving nothing but clean coal in the bottom bench.

The motive equipment in this mine consists of two 5-ton combination storage and trolley locomotives, and five 6-ton trolley and cable-reel machines. The mine cars are of the solid-box type equipped with roller bearings.

A headhouse has been built on each side of the branch, and the coal is discharged by a hand-controlled revolving dump. The car wheels have extended hubs which run under an angle bar on the dump and are thus held firmly in place. When the dump is empty the first car is run into it, and the entire device is turned off center by means of a large hand wheel. The dump then operates, the car remaining in an overturned position, where it is held in place by the angle bars.

#### CAR DISCHARGED ON REVOLVING TWIN DUMP

The opposite side of the dump is equipped with a similar arrangement of track and angle bars, and a car run into it is dumped in a similar manner. The dump moves through an angle of 180 deg., the weight of the loaded car bringing the empty to its original upright position. It is bumped off the dump by another loaded car, and the process is continued until an entire trip has been discharged, leaving an empty car hanging on the under side of the dump for the first car of the next trip to right. It requires but small effort on the part of the dumper to throw the first car over, and as there is but little machinery connected with this equipment, it has given splendid satisfaction ever since its installation.

From a small bin under the dump the coal is conveyed through an inclined steel tube 36 in. in diameter and 80 ft. long to a plate conveyer and thence to the shaker screens. A similar equipment is placed on the opposite hillside, and the coal is brought to a common point by the two conveyors, which together span the narrow valley.

On the east side of the branch a storage bin of about 300 tons capacity has recently been installed, being built over and around the steel tube. This is filled by means of a traveling feeder and loading boom so arranged as to allow the coal to go into the bin or

Fig. 4—One of the Horizontal Conveyors

These conveyors, of which there are two, furnish an excellent opportunity for picking extraneous material from the coal. Naturally some of the "jackrock" parting escapes the gob underground and finds its way to the surface.

FIG. 5

**The Tipple**

Coal is dumped into bins below the headhouses upon either side of the valley and slides gently down the tubular steel chutes to the horizontal conveyors, which transport it to the shaking screens in the tipple proper. Ordinarily three sizes are made, the two larger grades being lowered into the railroad cars by means of loading booms. Run of mine also may be shipped.

the tube at will. The rear end of this loading boom has no vertical movement and forms a picking table.

In operation each carload of coal is run over this picking table before another one is dumped and a man stationed there gives the coal its first cleaning. Though, of course, all the refuse cannot be removed at this point, yet this man can check up on each car that is dumped, and the management is able to tell exactly which men are loading dirty coal and make a fair estimate of the quantity of dirt loaded. A noticeable change for the better has been observed.

Again, the coal is let down to the bin with only a slight drop and slides down the sheet-iron bottom with small momentum. As a result there is no crushing or jamming of the coal at the bottom as is frequently the case when coal is dumped into a bin from a mine car direct. The bin can be loaded evenly from top to bottom and the coal slides freely throughout its entire length when it is being emptied from the bottom. As a result the product is transferred from the mine car to the shakers with little breakage. As soon as the business in sight demands it, similar equipment will be placed on the other side of the valley.

From the shaking screens the lump and egg sizes are delivered to railroad cars by loading booms. Four men are placed at each of these conveyors so that at this point the coal gets another picking. In addition two men are kept on each railroad car to remove whatever refuse has been overlooked by the others. An exceptionally fine product is the result.

By using different screen plates 2-, 4- and 6-in. lump, 2-in. and 2x4-in. egg, as well as screenings and mine run can be furnished. The egg coal is all rescreened before reaching the picking tables. Railroad cars are handled under the tipple by means of counterbalanced car retarders.

Power is furnished by the Kentucky & West Virginia Power Co. from its plant at Lothair, Ky. Current is transmitted at 3,300 volts to the local substation, where it is converted to 300-volt direct current by a 150-kw. Ridgway motor-generator set. This substation is built of cut stone and presents an extremely neat appearance, as do all the other buildings of this company.

The miners' houses are kept well painted and clean. All are supplied with running water and most of them have bathrooms. Consequently the dirt and disorder that make so many mining camps depressing are here conspicuous only by their absence.

### Bulletin Board Conspicuous Feature at Donk Bros. Coal Co.

A MINE property is not usually considered a picturesque place. The nature of its product and the equipment employed does not always present a pleasing appearance. Nevertheless, one is often pleasantly surprised to find a mine yard filled with well-designed buildings, and the miner provided with every convenience found in modern manufacturing plants.

The illustration shows the design of a bulletin board at the Thermal Mine No. 4 of Donk Bros. Coal Co.,

**Bulletin Board for Mine Yard**

This board attracts the workman to it because it shelters him from the sun, rain, or wind. Notices are always kept clean and dry so that they can be easily read.

near Edwardsville, Ill. The structure is permanently located near the mine shaft, being erected on a concrete platform. Shelter for the board and the workmen while reading the bulletins is provided. During the night or on dark afternoons the whole structure is lighted by electric lamps shown under the eaves.

The shelter and lights around this board attract miners to it and impel them read the notices which have been posted.

# Repairing a Broken Gear Tooth by Means of Studs

Several Ways Available for Repairing Broken Teeth—  
Studding Is the Simplest—An Accurate Template Is  
Necessary to Which Inserted Studs Must Be Fitted

BY G. H. RADEBAUGH  
University of Illinois, Urbana, Ill.

**G**EARS of cast or malleable iron are often damaged by the imperfect meshing of their teeth. To prevent unnecessary wear all gears should mesh closely. This means that their working centers must be definitely established and accurately maintained. Teeth in gear wheels are broken from overloading of the drive, from the dropping of tools between the teeth or from the wedging of other objects or substances between them.

Broken gear teeth can be repaired by any one of several methods: (1) If a tooth broken from the gear is in one piece it can be welded back into place by means of the acetylene torch. Such a job can be done most conveniently in a commercial welding shop. (2) This same type of break can be brazed in the mine forge. (3) A new tooth can be made and dovetailed into the gear. This type of job also can be done most effectively in a commercial repair shop. (4) A new tooth

When gear teeth are worn appreciably and some of them are broken some consideration should be given to the problem whether it would be cheaper and more expedient to obtain a new gear than to patch up the old one. If the teeth are not worn too much the old gear can be used as a pattern and a new gear cast from it. In preparing an old gear for use as a pattern it should be thoroughly washed in gasoline (Fig. 3) which removes all grease. The worn teeth can then be built out to the proper contour by using beeswax. Teeth that are missing, as in the gear here shown, can be shaped from wood and correctly positioned on the gear. The proper shape of the teeth can be gaged from another gear of the same pitch. The finished pattern can then be taken to a foundry and a casting made from it.

If it is decided to make the repair in the mine shop by inserting studs, the uneven surface left by the

Fig. 1—Inspection of Wheel

Anything that will break one gear tooth may break or crack others. When the damaged wheel has been removed from its shaft it should be carefully inspected and the entire extent of the damage done should be ascertained.

Fig. 2—Scraping off Adhering Dirt

Any exposed lubricated surface is a dust catcher. With a gear this material packs tightly between the teeth. A screw driver is an effective instrument for its removal, and it should be scraped away before repairs are begun.

Fig. 3—Removing all Grease

Before attempting to use an old gear as a pattern from which to cast a new one or before making other repairs, all grease should be removed from it. This may be one by washing the gear in gasoline which readily "cuts" grease.

may be thermit cast to the wheel. (5) A new tooth may be built up by acetylene or electric welding or (6) studs may be substituted for the broken tooth. This latter is the simplest method of repairing broken teeth in a spur or bevel gear. At best, however, it is only a temporary repair, but it can be made in the mine shop. The only equipment necessary is a drill and a few hand tools.

After the gear has been removed from its shaft a careful inspection (Fig. 1) should be made to see if other teeth have been broken or cracked. In the job illustrated it was found that grease and dirt had accumulated between the teeth and had become solidly packed there. This caused the gear to be crowded away from its proper working position. Power was then transmitted from a point near the tips of the teeth. This in all probability, was the cause of the teeth breaking. Packed dirt and scale should be removed. The best method is to loosen it up with a screw driver or some similar instrument, as shown in Fig. 2. After this has been done a much more thorough inspection can be made of the remaining teeth.

broken tooth must be removed. This can be done most expeditiously with a flat chisel and a square file as shown in Fig. 4. To assist in maintaining the location of the tooth the break should not be filed down too far; the outline of the tooth base should be left. Notice in Fig. 5 how prominently this tooth location appears. In succeeding operations the layout is gaged by this tooth outline. In determining what size of stud to use, the width of the tooth at its widest place should be measured. The stud should be of a diameter equal to this width or a little larger.

To obtain a good tooth layout, the surface may be chalked and a line drawn down the center of the tooth base. The dividers are then set to the required distance and the stud centers located. To provide for accurate drilling, the centers of the stud holes should be center-punched on the layout lines, as shown in Fig. 6. It always pays to take enough time to lay out the tooth correctly. If the hole centers are correctly located and properly drilled, the shaping of the studs is much easier than if the holes are drilled more or less at random. To patch a bevel gear is a much more difficult

**Fig. 4—Chipping the Tooth Base**

The uneven surface left by the tooth break must be removed before repair operations proper can be started. This work is most readily performed by means of the flat chisel and square file.

**Fig. 5—Laying out Stud Holes**

After the old tooth base has been smoothed off it should be chalked so that the stud-hole layout may be plainly marked. Attention to small details will often make subsequent operations easy.

**Fig. 6—Center-Punching the Holes**

In order to obtain a good finished job it is necessary that the stud holes shall be drilled accurately and in line. A careful layout and deep accurate center punching of holes are essential.

job than to make a similar repair of a spur gear. In the patching of either type of gear, however, it is necessary to maintain the proper location of the teeth.

This can be done most accurately by using a template made from cardboard or tin. A good template can be cut from a piece of extra-thin tin that can be sheared easily with ordinary cloth scissors. This kind of tin can be found in the lids of paint cans. To obtain an accurate layout of the tooth shape, the template should be made to cover or embrace three or four teeth. In laying it out as shown in Fig. 7 the outline of the teeth can be transferred to the tin by using a scriber or scratch awl. The template is cut to the required layout as shown in Fig. 8, care being exercised in following closely the layout lines previously made with the scriber.

Lines can be followed much more easily with the scissors than with tinner's snips. This is the reason for using the extra thin tin, as it would not be permissible to cut tin of usual thickness except with the snips. The template may be checked on the good teeth, as seen in Fig. 9. When putting in two sets of studs, as was necessary in the job illustrated, they must not only be shaped properly but should have the correct pitch, that is, be set the proper distance from the center of one tooth to the center of the next. The template, then, must fit not only the shape of one tooth at a time, but must fit on all the teeth. If it does not fit accurately, the shape of its contour can be corrected by filing or by trimming with the scissors.

After the template is completed, the holes in the gear are drilled, their location having been previously laid out. In selecting the drill a size should be chosen that will permit the tap to cut a full thread. In threading holes of this kind it is advisable to use the complete set of machinist's hand taps. These are made in sets

of three, each set consisting of a taper tap, a plug, and a bottoming tap.

In Fig. 10 the taper tap is shown in the hole starting to cut the thread. This tap is tapered for about half its length. The next tap to use would be the plug tap. It is used to thread holes through which it is impossible to run the taper tap. It is tapered for a length of about four threads. The bottoming tap, which follows the plug tap, has a full thread to its point. It is used in threading a blind hole to its bottom. All of these taps are of the same diameter and each will cut a full thread. It is commonly supposed by many that they are of different diameters.

#### BREAKING TAPS MAY CAUSE MUCH TROUBLE

Tapping a hole, especially one of small size, is a somewhat delicate operation, as there is always danger of breaking the tap. If used correctly taps should never break in service. In use the pull on the wrench should be equal on both ends. A tap should never be turned with one end of a wrench, as the pull is unequal, and an excess stress will be placed upon the tap, which may cause it to break. This is one reason why the use of a monkey wrench for tapping is never recommended. A good tap wrench will more than pay for itself in a short time.

Breaking of taps can be reduced greatly by proper lubrication. For tapping steel or iron a mixture of 10 per cent graphite and 90 per cent tallow gives good results. Machine oil is a less desirable tapping lubricant. For cast iron, lard oil may be used; however, any oil has the disadvantage of causing the chips to stick to the tap flutes. This may cause the tap to bind and tear the threads. Kerosene is often used when tapping cast iron.

**Fig. 7—Scribing a Template**

A piece of soft tin makes the best template. This is laid against the ends of uninjured teeth and their outlines or contours carefully scratched upon it by means of a scriber. The template should embrace several teeth.

**Fig. 8—Cutting the Template**

Ordinary paper or cloth shears or scissors should be used in following the scribed lines upon the template. They will perform more rapid and accurate work than will common tin snips, but the tin used should be light.

**Fig. 9—Trying the Template**

In order to be of value a template must be accurate. After it has been cut out with the shears it should be tested on the gear teeth and any inaccuracies found should be corrected either with the scissors or with a file.

Removing a tap broken off in a hole is a job requiring much skill. In Fig. 11 is shown one of the best methods for removing broken taps. It often happens, however, that this scheme will not loosen the tap, and other methods must be employed. When trying to remove a broken tap with two punches as shown, most failures result from too strong and unequal blows from the hammers. It should be remembered that extremely light blows delivered simultaneously and with equal force generally will remove the stub; heavy unequal blows delivered separately accomplish little.

Fig. 10—Tapping the Stud Holes

If possible a tap wrench should be used, to either end of which an equal pressure should be applied. Using a monkey wrench or other means of turning a tap is liable to cause trouble.

Fig. 11—Removing a Broken Tap

Taps should be amply strong, but they sometimes break. In most cases they can be backed out by light simultaneous blows delivered to punches placed on opposite sides of the broken portion.

Fig. 12—Threading a Stud

Though commercial cap screws may be used, repair studs generally should be made from rod stock. After the thread has been well started the die should be reversed, cutting the thread to a shoulder.

Another method sometimes used to remove broken taps is that of annealing the tap stub and then drilling it out. This method involves heating the entire job and consumes much time. Dilute nitric acid, in the proportion of about one part acid to five parts of water, injected into the hole loosens the tap so it usually can be removed readily. The acid mixture, however, should be thoroughly washed out of the hole, as otherwise it will continue to eat the threads. Before re-entering a new tap, one should be absolutely sure that no fragments of the broken tap remain in the hole.

When the holes have been tapped, they are ready to

half in two, making the stud a little longer than required. This extra stock is left for finishing.

The ordinary method of cutting off metal is to use a hack saw. The blade is held in a frame deep enough to allow the severing of any ordinary thickness of metal. For most work the hand frame is used, the workman operating the saw with a back-and-forward stroke while the work is held in the vise or in some other convenient position, as shown in Fig. 13.

The hard service required of hack saws demands that the material of the blades be of the best and that the number, shape and set of the teeth be carefully con-

Fig. 13—Cutting Stud to Length

After the stud is threaded the rod may be placed in the vise and sawed partly in two. It should be cut slightly longer than needed for the finished tooth, the surplus length being removed by a file.

Fig. 14—Screwing in the Stud

A stillson or trino wrench may be used on the partly sawn-off rod to force the threaded end home. When screwed to place it is absolutely necessary that the stud be tight and solid in the tapped hole.

Fig. 15—Breaking off the Rod

When the stud has been screwed home the rod may be broken from it by bending back and forth. It was to facilitate this severance from the stud that the rod was cut partly in two after it was threaded.

receive the studs. Standard cap screws can be used for these studs but are more expensive than studs made from a piece of round stock. The best way to make a stud so that it will fit into the hole already tapped, firmly and without play, is to cut the thread with the die matching the tap used. The thread should be started on the end of the rod, which previously has been rounded off on the grinding wheel or with a file, with the stock and die in the usual position, that is, with the taper down.

It is obvious that the best work cannot be done on all kinds of metals with the same saw. Some are adapted to cutting hard, brittle metals, whereas others are suited to soft ones. It is also apparent that some saws work most advantageously on thin sheets and others on heavy sections. The blade should be well stressed in the frame with the rake or the teeth forward. Downward pressure should be exerted on the forward stroke so that the blade will "take hold." A lighter pressure is applied on the return stroke. A

blade should never be bent sidewise and the saw should be operated at about fifty strokes per minute. By keeping the saw as nearly as possible in the plane of the cut and thus avoiding wrenching it, the number of blade breakages will be reduced.

After the saw cut has been carried half way through the rod the threaded end is screwed into position, as shown in Fig. 14. The rod is then broken from the stud, as shown in Fig. 15. Whenever possible, that is, if the stud is screwed through the wheel rim, the end should be riveted over. This makes a much stronger job.

The studs, however, can be rusted in place. This can be done by applying to each stud before it is started in the hole a rust cement. By using such a cement galvanic action sets in quickly and the iron swells, through the formation of iron oxide, thus securely fastening the stud and gear together. The most common of rust cements is made with 2 parts of sal ammoniac, 1 part sulphur, and 60 parts iron dust or filings. These ingredients are mixed and water containing  $\frac{1}{2}$  part vinegar is added until a paste is formed.

The stud must screw into the tapped hole "good and tight." A loose fit will not do at all; if the stud fits loosely the die should be adjusted to cut a larger thread. Studs are screwed into all the holes and are then filed to the shape and position called for by the template, as shown in Fig. 16. The best file to use on a job of this kind is the half round, bastard cut. It is much easier to shape the studs with the half-round file than with other shapes, as, with it, it is possible to work on their sides as well as on their tops.

Fig. 16—Filing to Template

After all studs have been inserted they are filed to the proper contour. Frequent use should be made of the template during this operation to make sure that not only the contour but the pitch is correct.

Fig. 17—The Finished Job

When all studs have been filed to the correct contour and pitch and the template fits accurately, the job of repair is finished. The gear may now be returned to its shaft and be put again into service.

If the job checks with the template, it is ready to be put back in service. Attention is called to the finished job as shown in Fig. 17. In this case seven studs were required to make the patch. After the gear is re-mounted on the shaft and put in mesh with its running mate, the drive should be turned over by hand and the job checked to be absolutely sure the studs mesh properly with the gear. If they bind, the high spots will be clearly defined by friction marks. These should be filed off before power is applied.

Such a repair as has been described must of course be considered as being of a temporary nature only. In coal mining, however, where the attainment of output in large degree determines the cost per ton, and delays are consequently expensive, such a repair as has been described may be the means of keeping some important piece of machinery going until a new pinion or gear can be procured. Under such circumstances even the crudest of repairs, provided they keep the mine in operation, may be fully justified.

## Cinderella Miners Build Swimming Pool

CO-OPERATION between employer and employee has rarely been better exhibited than by the Sycamore Coal Co. and its employees during the past three weeks of July. Early in July the employees of the Sycamore Coal Co., at Cinderella, asked the management for a swimming pool. They offered to furnish all labor necessary for the completion of the job if the company would furnish the necessary materials. This the man-

Dedication of Swimming Pool at Cinderella

After everyone had taken a swim the kiddies were given their fill of lemonade and ice cream and still later a picnic supper was served by the ladies to all those present.

agement agreed to do on July 8 and on July 9 actual construction started.

About seventy men and boys turned out to work on the pool, and hammers and saws were kept busy during the evenings and on idle days until the forms were completed.

On July 22 the concrete for the walls was poured and

Diagram of Pool Showing Top and Slide Elevations

on the nights of July 25 and 26, the concrete for the bottom was placed, the actual construction work being finished just seventeen days after work was begun. quite an achievement when one takes into consideration that the men worked only in the evenings and on idle days.

The pool is built throughout of reinforced concrete and measures 32 x 72 ft. The main compartment is 30 x 60 ft., being 6 ft. deep at one end and gradually sloping up to 3 ft. at the other end. A novel feature of the pool is the separate compartment for the little tots. This part of the pool measures 10 x 30 ft. The deepest point in this compartment is 2 ft. and it slopes to a feather edge. This makes it possible for the little children to paddle around in the water just as well as the grown ups. The pool was formally opened on Aug. 2, before several hundred people.

Beech Bottom Slate Dump

## Aerial Tramway Solves Rock Disposal Problem

Tramway 3,200 Ft. Long—Dumping Point 200 Ft. Higher than Coal Bed—Little Power Required for Operation—Only Four Men Needed to Dispose of 400 Tons of Slate per Shift

BY ALPHONSE F. BROSKY

Assistant Editor, *Coal Age*  
Pittsburgh, Pa.

OF ALL THE operations incident to bituminous coal mining, least effort, as a rule, is expended in the attempt to effect economies in the handling and disposal of mine rock on the surface by the use of labor-saving machinery. Were operators to give more consideration to better ways and means for transporting refuse from the mine mouth or tippel to the dumping ground, and stowing it there they doubtless could save at least a few cents on every ton of coal produced. At those operations where 100 tons or more of rock is handled above ground every working day no system that does not employ labor-saving machinery should be considered.

Mine cars filled with rock can be dumped into bins in or near the tippel. From thence this refuse can be transported by electrically propelled conveyances that automatically discharge their contents at some predetermined point. There is no excuse for tramming by man or mule power along any portion of the distance between the points of loading and discharge.

Hand-shoveling and the utilization of hand-operated cranes at the dump are expensive methods of removing rock from mine cars. In short, means in use for performing this work ten to 50 years ago should not be countenanced today. Aerial tramways are well-suited to this purpose whether the ground over which they operate is hilly or level. Typical layouts of such tramways installed at coal-mine plants are shown in Figs. 1, 2 and 3.

About four years ago, when the Windsor Power House Coal Co., a subsidiary of the West Penn Power Co. and the American Gas & Electric Co., took over and rebuilt the plant known as the Beech Bottom

mine, near Wheeling, W. Va., it was faced with the problem of disposing of large quantities of mine refuse. The roof in this operation which works the Pittsburgh No. 8 bed, is unsound; consequently much of it must be taken down, close timbering is required and cleaning up falls is part of the day's work. Much of this roof rock particularly that removed from entries, must be taken to the outside. Eleven tons of slate must be hauled to the surface for every 100 tons of coal mined. As this operation produces 3,300 to 3,500 tons of coal per day, an arrangement was sought that could dispose of 300 to 400 tons of rock per shift.

### SLATE DUMP SOME DISTANCE FROM TIPPLE

The ground best-suited for use as a slate dump lies due south of the tippel, in the form of a wide valley sloping westward toward the Ohio River. The hills flanking this depression upon either side rise to an elevation of about 200 ft. above the coal bed. This topography favored the adoption of an air route to the dumping point, and accordingly an aerial tramway was selected for the disposal of mine refuse. A profile of the ground over which this line extends is shown in Fig. 1. The ground plan of the tramway also appears in this figure.

Prior to the installation of the aerial tramway, the rock was hauled in mine cars to the brink of the dumping ground and there discharged into side-dump, V-body slate cars. These were lowered by gravity to a dump in a ravine and pulled back by a hoist. This system required three shifts of five men each. The present method of slate disposal requires the services of only four men on one shift. One of these inspects the ropes and attends to their lubrication as well as that of other parts of the tramway. He also makes any minor repairs that may be needed. The other three men are employed in the loading terminal, receiv-

NOTE—In the headpiece is shown the dumping ground for the slate and rock removed from the Beech Bottom mine. The tram buckets pass around the tail terminal sheave located in the tower on the extreme right. In making this turn they are not detached from the traction rope. The tippel lies beyond the hill to the left.

ing, loading and dispatching the buckets. This saving in labor is in itself ample justification for the choice of the aerial tramway.

Aside from the labor required at the loading station, (which in reality is part of the tippie) the system is automatic. Chutes and gates under a two-car revolving dump are designed so that rock from either or

terminal. To negotiate successfully this change in horizontal direction without aid from an attendant, an angle station was built. This was arranged to give a change of 11 deg. 26 min. in a vertical plane. Because the greater angle is in a vertical direction the downward pull on the rope keeps the buckets from being derailed at this station. Rollers are set at the proper

Fig. 1—Plan and Profile of the Beech Bottom Aerial Tramway Showing Present Dumping Point

Not only is the point of bucket discharge movable along the tramway, but as the valley is filled with mine refuse the course of the cableway may be changed as indicated. The capacity of such a dumping arrangement is thus large.

both cars can be bypassed into a rock bin. Adjoining this bin is the loading terminal of the aerial tramway. Buckets, running on track cable suspended from towers, are attached at intervals to an endless traction rope which pulls them from the loading terminal to the dumping point (where they are discharged automatically), thence to and around a tail terminal and back again to the loading point. This tramway is of

angle and elevation at this point to guide the traction rope around the curve in the absence of buckets. From the angle station the buckets travel out over a 1,400-ft. span of cable where the mine refuse now is being dumped.

In addition to the angle station four towers, three of two-bent and one of three-bent construction have been built, as shown in Fig. 1. The three-bent tower A is located about 400 ft. from the loading terminal whereas those consisting of two bents namely B, C and D are respectively 570, 1,600 and 3,000 ft. from the loading point. These structures are all of steel and supported on concrete piers carried down to a solid footing.

The main members of the sub-structures consist of heavy angles securely tied and braced with smaller ones. Corresponding members of the head-structures are fabricated from channels similarly braced. The beams on which the track-cable saddles rest are channels bolted to a supporting column. These uprights extend to the horizontal members of the sub-structure. Each tower is provided with a conveniently located ladder, used by the tramway crew when oiling traction-rope rollers, inspecting saddles or making repairs.

A  $\frac{5}{8}$  in., 6x7 crucible-steel wire, Lang-lay traction rope is used. The track cables are of the locked-coil type. They have a diameter of  $1\frac{3}{8}$  in. on the loaded

Fig. 2—Typical Level-Ground Aerial Tramway

It is easier to build up a rock bank by dropping material from buckets suspended from a cable above it than to grade up tracks from the ground level.

the Trenton-Bleichert type and was built by the American Steel & Wire Co.

This installation is designed for an ultimate capacity of 80 tons per hour. To obtain this capacity the buckets are spaced 230-ft. apart or at a time interval of  $40\frac{1}{2}$  sec. It is now, however, transporting 40 tons hourly, the intervals of time and distance between buckets being twice those given for the ultimate capacity. A 30-hp. slip-ring induction motor is required to operate the tramway at a rope speed of 340 ft. per minute when carrying 80 tons per hour. At half-capacity, however a 15-hp. motor is sufficiently large.

This tramway is 3,196 ft. long horizontally and rises 207 ft. to the tail terminal. It is unusual in that a change of 8 deg. 21 min. is made in the alignment at a point approximately 1,400 ft. from the loading

Fig. 3—Aerial Tramway Assists Electric Larry

At Jenkins, Ky., ropes and buckets are utilized to attain sufficient height on a hillside so that mine refuse may be wasted by means of an electric larry.

side and  $\frac{7}{8}$  in. on the return side. The main advantages of this type of track cable for use on tramways are: It cannot unwind and should an outside wire break it cannot project to derail a bucket; its smooth exterior surface does not groove the carriage wheels as do other types of rope; a short section can be repaired by coupling in a new piece. This is a replacement that cannot be accomplished with ordinary rope.

The track cables are suspended from the towers by means of rocking saddles, each consisting of a cast-iron base supported by a beam. Upon this base the saddle proper is set, the design being such that the saddle can rock more or less. The saddle proper is a steel casting that provides a long easy curve for the cable to rest in, accommodating itself easily to the changing angle of the rope as the load approaches or recedes from the supporting tower.

The track cables are lubricated by an oiling machine that travels on the ropes in the same fashion as the buckets. Oil in a tank under a pressure of about 35 lb. per square inch is forced through a piece of flexible steel hose to a valve located between the two carriage

At the tail terminal the traction cable passes around a 12-ft. sheave built up of structural shapes. The rim of this sheave is channeled to allow the grips on the buckets to seat themselves properly without being detached as they move around.

In order to keep the traction rope at a tension that will prevent the rope from slipping on the grip sheave, as well as to compensate readily for any stretching of the cable a movable sheave is provided. This is supported in a frame to which a block of concrete is attached by means of a heavy steel tie-rod. Under this concrete block, cribbing is placed so that the position of the sheave may be varied somewhat up or down. With this arrangement the tension on the traction rope is fixed at all times by the position of the counterweight.

#### STATIONARY DEVICE ATTACHES BUCKET TO CABLE

Standard self-dumping 20-cu.ft. buckets are used on this tramway. The trunnions are placed below and slightly to one side of the center of gravity, causing the bucket to overturn upon release of a latch and to

FIG. 4

#### Loading Terminal

This is the only place where the buckets are detached from the traction rope. While passing through this station the buckets are pushed by hand, moving always in the same direction and traversing roughly a half circle from the ungridding to the gripping-on point. Three men can easily load and dispatch 400 tons of rock per shift. The buckets hold 20 cu.ft. of material.

wheels. As the oiler travels along the cable a knocker on the carriage wheel comes in contact with an arm which opens the valve. At each such opening a certain quantity of oil is squirted onto the track cable.

These oil ejections form practically a continuous stream when the machine moves at full rope speed, yet the flow ceases when the oiler comes to rest. The traction rope is kept well-lubricated at all times by running over a small vertical sheave that is partly immersed in a tank of oil. This sheave is located in the loading terminal.

Motion is transmitted to the traction rope by a 6-ft. drive sheave of the gripping type. This sheave is fitted with seventy-two pairs of cast-steel jaws that engage the traction rope making it impossible for it to slip. These jaws are of such shape that the rope is gripped without being damaged. The sheave is mounted on a vertical shaft fitted with suitable bearings and is driven by a train of bevel, pinion and spur gears through a countershaft and a silent chain from a motor. A 40-in. brake wheel is mounted on the pinion shaft.

remain in the capsized position until the loading terminal has been reached. Here it is righted by the crew in attendance at that point.

The hangers, on which the grips are mounted, are fabricated of flat steel. At the bottom of the hanger arms, the steel-casting trunnions are attached so that the buckets swivel or turn upon them. The carriages are equipped with steel-casting wheels fitted with bronze bushings which turn on mild-steel pins. These pins are provided with grease cups, and lock washers keep the nuts from coming off.

The grips are of a type that open on the top. They are designed to hold tightly against a horizontal pull of 1,600 to 1,800 lb. The main, or body, casting is made of iron, and the links, operating lever and movable jaw are steel castings. The movable jaw is equipped with a  $\frac{1}{8}$ -in. flat steel liner spring and a back liner of tool steel mounted in the body casting. When necessary, these liners may be replaced easily.

The traction rope grips are applied by an operator who pushes the bucket past a device known as an attacher. This is a steel casting against which the roller of an

Fig. 5—Compound-Angle Station on Top of Hill

In passing this tower the direction of travel of the buckets is changed in two planes. The vertical angle is made the greater so that the traction rope cannot pull the bucket wheels off the track cable. Rollers guide the traction rope through this station.

operating lever bears. Because this casting is spirally shaped, it closes the grip by applying pressure to the operating lever that rides over it. The traction rope where it passes the attacher, being on a slope, is forced against the grip causing it to rotate in its trunnions and the rope to be seated properly before being gripped. The detacher is a somewhat similar device except that it moves the operating lever in the opposite direction, thus opening the grip.

A signal gong is provided to notify the operator when to attach the buckets in order to maintain an equal spacing on the line. This device consists of a base plate on which suitable gears, a knocker arm, cap, etc., are mounted. It is actuated from the main shaft of the grip sheave, and each sounding of the gong is the signal that a bucket is to be gripped on and sent out on the line. The buckets are discharged by a movable tripping frame mounted on the track cable. The latches that hold the buckets in an upright position are released by tripping arms and the buckets revolve on their trunnions emptying their contents into the ravine below, the buckets, of course, continuing to travel meanwhile at a uniform speed of 340 ft. per min. They pass around the 12-ft. sheave at the tail terminal and return to the loading point, where they are detached from the traction rope and pushed to the loading chutes. After being

Fig. 6—Tail Terminal and Domestic-Storage Bin

Tension on the traction rope is regulated by raising or lowering the concrete counterweight block, and inserting or removing crib timbers below it. The tramway buckets are utilized for transferring domestic coal from the tippie to the cylindrical bin in the background. This supplies the company's town nearby.

loaded they are pushed to the attacher which closes the grips and another trip is begun. From the foregoing it will be noted that the buckets are detached from the traction rope only while passing through the loading terminal.

In addition to the disposal of mine refuse, this tramway serves another purpose: it conveys coal from the tippie to a large steel-tank storage bin located near the rail terminal. From this bin coal is drawn for domestic purposes in the company's town nearby. An additional tripping frame is attached to the track cable directly over this tank.

When correctly designed and installed an aerial tramway such as has been described is desirable for transporting and dumping mine rock chiefly for the following reasons: (1) The buckets run on rope track, which is more or less flexible because it is loosely strung from tower to tower. This eliminates the obvious difficulty encountered in keeping rigid and to gage a rail track on shifting slate banks. (2) Cables can be strung in the shortest distance between two points—over level ground, uphill or downhill—whereas ground systems or track rails are applicable to easy grades only. (3) Potential dumping capacity for a single set-up is many times that of other systems.

### Parr Defines Conditions Favorable to Heating of Coal in Storage

S. W. PARR has furnished the American Chemical Society a summary of his findings on "Deterioration and Spontaneous Combustion of Coal in Storage" as a basis for the round-table discussion on that subject, Sept. 11, at the Ithaca meeting:

1. A high percentage of textural moisture in a coal indicates a high capacity for oxygen absorption. Such coals immediately upon breaking out from the seam begin to lose moisture until an equilibrium with the moisture of the atmosphere is established, thus making way for the accession of oxygen.

2. The larger the lumps of coal the slower the interchange as between the free or inherent moisture and oxygen. Conversely, the more finely divided the material the more rapid the interchange and also the greater the superficial area of the coal particles.

3. Any departure from normal temperature upward, unless checked or dissipated, is a vital factor, whether such increase of temperature arises from external sources or is the result of chemical combinations within the coal itself.

4. Accessibility of air within the coal mass, thereby augmenting the supply of oxygen beyond the quantity taken up by absorption, is essential for carrying the oxidation forward, thus bringing the temperature of the mass up to the point of ignition.

5. Accessibility of air involving ready circulation to an extent which will carry away the initial increments of heat as rapidly as formed will prevent a rise of temperature.

6. Complete prevention of an additional oxygen supply beyond that absorbed by the coal before entering the storage pile will insure against any appreciable or dangerous rise of temperature.

7. The oxidation of pyritic sulphur requires the presence of free moisture as well as oxygen. The augmenting of the heat in any manner greatly accelerates the oxidation processes for both the hydrocarbon and the sulphur components of the coal.

# Latest Improvements in Locomotive Control

Developments of New Controllers Due to Use of Larger Currents and Necessity for Power Economy—Electro-Magnetic and Electro-Pneumatic Contactors on Large Locomotives—Field Control Provided for Storage-Battery Motors

By H. H. JOHNSON\*

FOR SOME fifteen to twenty years, control equipment for standard mine locomotives underwent practically no change. It is only in the last year or two that the design of the equipment has been modified. The long period of stagnation was not the result of complete satisfaction with the systems then developed but was due rather to the fact that the use of drum controllers on early types of locomotives became a precedent from which no one was ready to depart and also to the fact that power economy during acceleration and slow-speed periods had been given little consideration.

The power losses of railway equipment during the acceleration period were given consideration early in the art of electric traction. The first steps taken were to meet the necessity of getting the motor or motors directly on the line as soon as possible. This brought into use the rheostatic control system and the controller known as the type R, which partly answered the purpose. It was soon apparent, however, that a more efficient system than the rheostatic method of acceleration was necessary if greater economy in power was to be attained. With this in view, the series-parallel controller known as the K type, was adopted after much development. This type of control first employed the open-circuit system of transition and later employed the shunting method so as to effect smoother acceleration. Later the bridging system of transition was adopted for the purpose of obtaining still further improvement.

As railway equipments increased in size a still heavier and more economical type of control soon became necessary. The desire to operate cars in trains also required a system of remote control. Both of these conditions promoted the development of the two commonly known systems of electro-pneumatic and electro-magnetic control, which now are being used widely with all sizes of motor equipment.

Throughout this evolution of the railway control systems the development of mine- and industrial-locomotive control practically remained at a standstill. There are three reasons for this: first, the increase in mine locomotive motor capacities had not increased beyond the satisfactory limits of the drum controllers; second, the class of labor in mines had not been capable of handling more refined or complicated electrical equipment; third, the type R controller had been smaller than other types having the same rugged characteristics.

The more recent increase in locomotive sizes and capacities, and the general tendency toward the lower of the two commonly used voltage systems, namely, 500 volts and 250 volts, has made it necessary to develop suitable control equipment for handling the heavier currents at these voltages. Improvements in the caliber of the electrical staffs of mining companies has permitted, to a large extent, more refinement in locomotive

control, and a study of economy and maintenance has prompted the development of better control for larger motors.

Gathering and haulage types of locomotives are now defined by a relatively sharp line of demarcation. It is in the latter class of locomotives that the large increase in size has taken place. In some instances the increase has taken the form of large single-unit locomotives but in other cases tandem and multiple operation of small units accomplishes the same purpose. The general tendency will lead ultimately to multiple operation of small units rather than to operation in tandem.

With series-and-parallel control the motors may be accelerated either in series or in parallel at the will of the operator. It is evident that, when the starting resistor is designed to start the motors in parallel, the starting tractive effort will be approximately twice

Fig. 1—Operating Curves of Series-and-Parallel Controller for Five-Ton Locomotive

This diagram shows the characteristic curves of a 5-ton locomotive equipped with two 250-volt motors when operated by a type R controller. It is the usual practice of the operator to start the locomotive with the motors connected in parallel, instead of in series; consequently, the power used when accelerating the load is excessive.

\*General Engineering Department, Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa.

as great when the connections are changed at the controller so as to start the locomotive with the motors in series.

On the other hand, if designed to start the motors in series, the number of effective notches when starting in parallel will be reduced, as unnecessary resistance must be cut out, before effective work is done by the locomotive. This condition makes it difficult to obtain satisfactory starting, with both connections when the resistor is designed to give the proper starting characteristic with either one of the two. This has practically resulted in straight rheostatic acceleration, and the operative usually leaves the connections so as to start always with the motors connected permanently in parallel. Fig. 1 shows the operating curves of the motors when connected in series and in parallel. The curves are based on the starting resistors being figured to start the motors in parallel.

In the series-parallel type of control the motors must

reduced, it becomes necessary to allow the current to drop after each notch has been taken so that the succeeding increase of current will not be sufficient to cause the wheels to slip. This reduces the average tractive effort during the acceleration period.

The application of manual control is limited to relatively small capacities, largely on account of danger to the operative and the difficulty of manually operating a large controller. Remote control is desirable for large capacities, that is, in general where the total capacity exceeds about 300 hp. at 500 volts, or 150 hp. at 250 volts.

Series and parallel controllers are obtainable, that are suited for operating two-motor equipments using two 85-hp. motors on 250-volt circuits. For four-motor equipments series-and-parallel controllers are available for four 65-hp., 250-volt motors. Four-motor controllers are usually required for tandem operation of two locomotives. For three-motor locomotive equipment, controllers are available

for capacities up to three 120-hp. motors at 500 volts or three 60-hp. motors at 250 volts.

The type K controllers are built for two- and four-motor equipments up to and including a maximum of four 110-hp. motors at 600 volts or four 45½-hp. at 250 volts. These controllers are used extensively in railway work and from the standpoint of safety it is usually considered desirable to limit their use to four-motor equipment of 50 hp. per motor at 500 volts. For larger sizes remote control is recommended.

Series-parallel connections are used with the type K controllers.

They also use the shunting method of transition from series to parallel. This type of controller has the advantage of the economy incident to the use of series-parallel control which results in more notches for the same controller capacity. Height limitations for railway applications were not of much importance, but in attempting to use this type of controller on mine locomotives height is usually a vital consideration and it is impractical in many cases to use a high controller of the K type.

Controllers designed for resistance braking or resistance and magnetic braking have been built for railway application for two- and four-motor equipments up to and including a total of 200 hp. at 500 volts. Series-parallel acceleration is provided, and the braking is secured by moving the operating handle in a counter-clockwise direction from the "off" position. This method of dynamic braking is the most desirable for mine locomotive service. Unfortunately this feature adds still further to the height of the controller and is largely the reason for not making use of the original

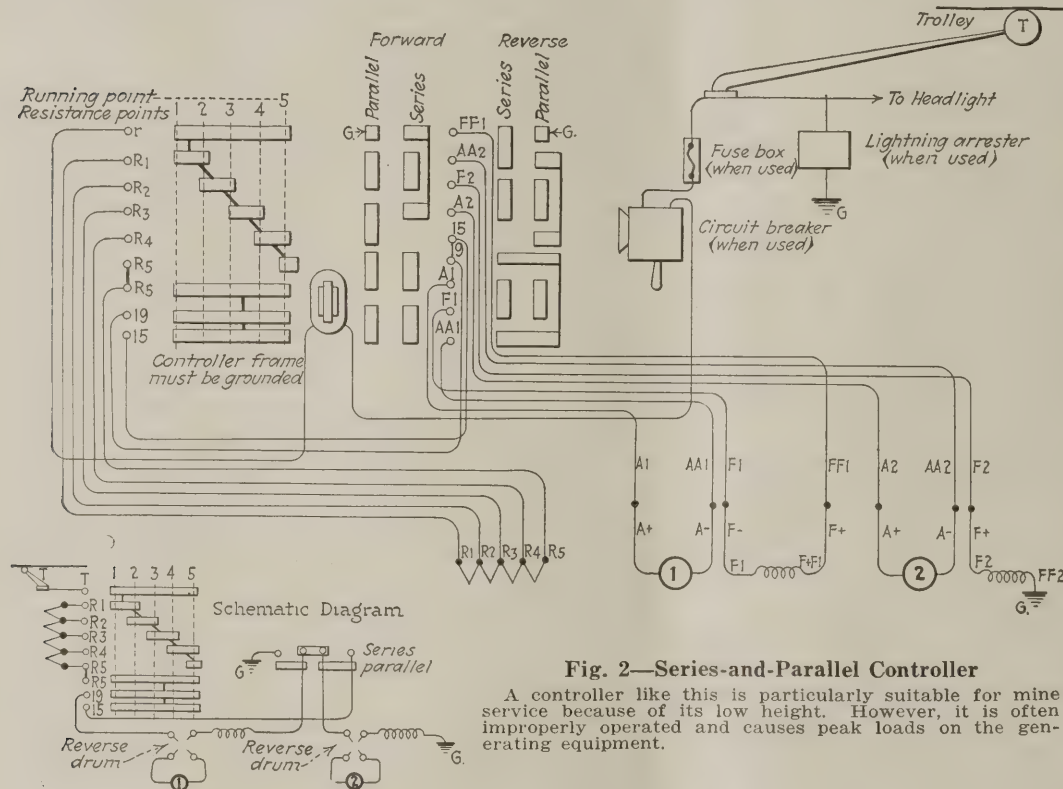

Fig. 2—Series-and-Parallel Controller

A controller like this is particularly suitable for mine service because of its low height. However, it is often improperly operated and causes peak loads on the generating equipment.

be started and accelerated in series until all resistance is out of circuit, then a portion of the resistance is re-introduced and the motors connected in parallel, after which the resistance is notched out. This results in lower power consumption during the acceleration period and allows economical running speeds below full speed.

Series-parallel control is very desirable from a standpoint of efficiency but it has not been widely used in mine-locomotive applications chiefly because of the increase in the controller height. A series-parallel controller of the same rated capacity as a series-and-parallel controller has more notches. The number of notches available on the controller affects the maximum weight of train which a locomotive can pull.

Maximum tractive effort is determined by the slipping of the wheels. If the controller has an infinite number of notches, the accelerating current may be kept so that the variation from the maximum tractive effort is infinitely small when notching from one point to another. If the number of notches on a controller is

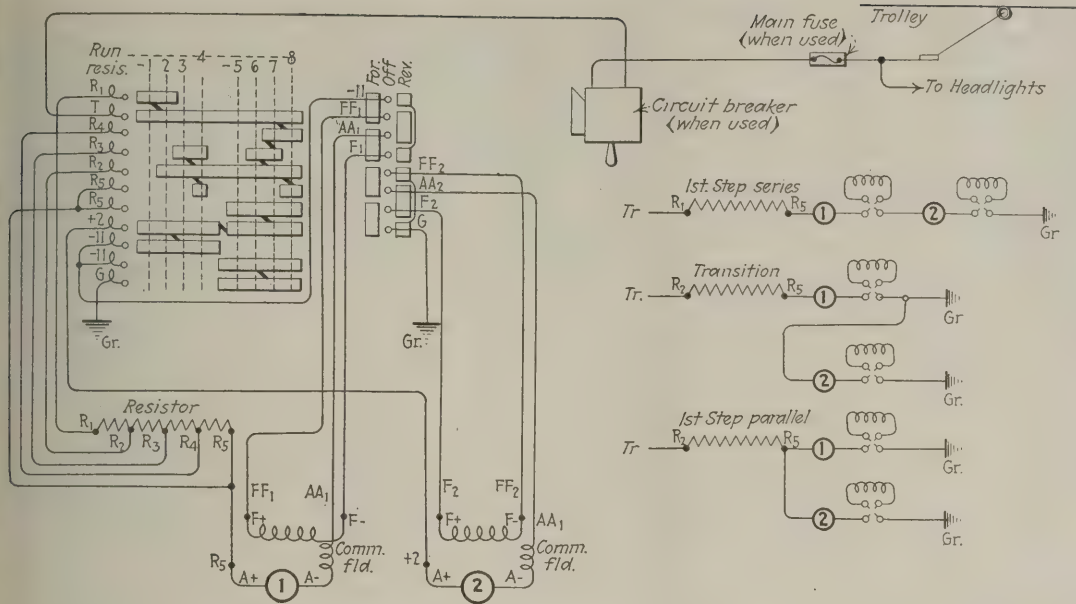

Fig. 3  
Later Type Unit

The series-parallel controller gives better acceleration of the locomotive and train. The operative must start with the motors in series and pass over each consecutive notch until the motors are finally in parallel across the line. This saves power when the locomotive is being accelerated or is running at less than the speed for which it is designed.

features of the braking type of controller developed for street and interurban traction service.

Fig. 3 illustrates connections for a controller developed for, and in use on, storage-battery locomotives. When selecting controllers for storage-battery locomotive service it is of great importance to take into account battery economy. As many of the speed-control points as possible should be obtained without the resistance of the starting rheostat being in the circuit. The use of field control is of great economic value and permits greater speed variation which less battery consumption.

Line switches have been used effectively in conjunction with drum-type controllers to relieve the drum contacts and fingers of arcs when breaking the main circuits and returning the controllers to the "off" position. The line switch, when used in this manner, may also be made to provide for overload protection, used in conjunction with an overload relay. Line switches have been used extensively with street-railway equipment but not much on mine locomotives. Line switches are either made up of contactors which are of the electro-pneumatically operated type or the straight magnetic-

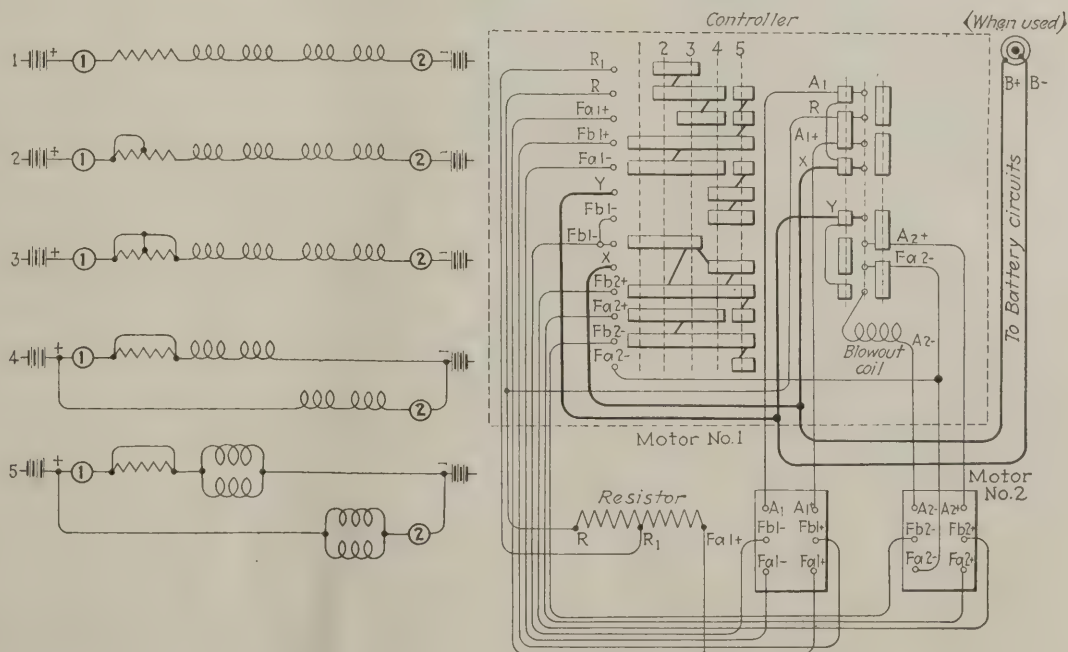

contactor type, usually depending upon the service.

The electro-pneumatic unit switch differs from the energizing a solenoid from the control circuit. One of the main circuit contacts is carried on an extension of the armature, and as the armature is drawn upward by the solenoid it completes the main circuit through a stationary contact. When the solenoid is de-energized the armature drops by gravity. A magnetic blowout is provided for extinguishing the arc. The whole switch mechanism is mounted on a base and placed in a sheet-steel box.

The electro-magnetic type of contactor is closed by magnetic contactor in the means employed for operating the switch contacts. High-pressure compressed air is admitted to a cylinder, the piston of which is attached to the moving contact arm. This piston moves against the action of a powerful spring. When the air is released from the cylinder, the spring forces the switch jaws apart with a force of over 100 lb. and an effective magnetic blowout extinguishes the arc. The circuit is quickly broken because the switch contacts open at high speeds.

FIG. 4  
Storage-Battery Controller

Every possible means for obtaining the maximum of useful work from the storage battery should be incorporated in the controller used on a battery locomotive. By means of field control many resistance points are eliminated, and it is possible to vary the speed widely without undue draught on the power of the battery. Economy in power increases the length of time that the battery can be run, thus adding increased convenience to economical operation.

#### Improved Type Overload Relay

Such a device for use on a mine locomotive should be rugged and positive in operation. Locomotives of large size should invariably be provided with some means of preventing the controller fingers from seriously burning.

One hundred pound pressure at the contact surface insures positive action of the switch. Air is admitted to, or released from, the cylinder through a valve operated by a small solenoid. The whole switch mechanism is mounted on, and insulated from, a cast-iron framework and enclosed in a sheet-steel cabinet. The chief advantages for mining applications are powerful and positive action of switch movements; effective blowout; contact pressures independent of line-voltage fluctuations; low maintenance; and rugged construction.

With the recent increase in demands made on mine locomotives, drum control has been taxed to the limit and a more satisfactory means of governing the larger motor equipment was necessary. This has been the cause of the introduction of remote control for units of large capacity. Many satisfactory applications have been made and both magnetically-operated contactors and electro-pneumatically operated contactors have been used. Included among the many advantages of remote control the following are outstanding: 1. Greater motor capacity may be handled. 2. Maintenance cost may be reduced. 3. Controller manipulation is made

Fig. 6—Section and Rear View of Electro-Pneumatically Operated Contactor

The high currents necessary with locomotives of large capacity make it impossible to develop a practical manually operated controller. This contactor operates from a small control circuit. All heavy currents are broken between large contacts provided with arcing chutes and blowouts.

Fig. 7—A 35-Ton, 250-Volt Single-Unit Mine Locomotive

Each of the three axes is driven by a large motor. The control consists of electro-pneumatic contactors which are also used to provide dynamic braking. Mechanical braking is obtained by air brakes.

easier. 4. Danger to operative is reduced. 5. Multiple operation of two or more locomotives is made possible with slight addition of equipment. 6. Minimum headroom is required and 7. Overload protection is increased by the opening of the switches.

### British Government Will Study Coke, Benzol and Gas Manufacture

The government of Great Britain, at the instance of the Secretary for Mines and the Department of Scientific and Industrial Research, according to advices received by the Bankers Trust Co. of New York from its English Information Service, has decided to provide at once for the rapid development of a chemical and physical survey of the coal seams of Great Britain, to determine the possibility of replacing some 140 million tons of raw coal at present burned every year in its natural state by other and smokeless fuels obtainable from coal by carbonization and gasification.

It is pointed out in this connection that if coal could be carbonized on a large scale in such a way as to yield a supply of fuel oil for the navy and mercantile marine, and an important share of motor spirit for use in motor cars and aircraft, the balance of foreign trade would be altered in favor of Great Britain. The abatement of the smoke nuisance in towns and manufacturing districts owing to the abandonment of raw coal as a fuel would have immediate and far-reaching effects upon the health and housing of the people.

**SULPHUR IMPORTANT SOURCE OF HEAT IN SPONTANEOUS COMBUSTION.**—S. W. Parr and E. R. Hilgard will say in the paper they will deliver at Ithaca, Sept. 11, before the American Chemical Society, that finely divided pyritic sulphur which may be even in microscopic sizes is more common in coal than has been supposed. A high percentage of sulphur is often associated with mother of coal and in Illinois sulphur in marcasite form is quite as abundant as in the pyritic form. As the oxidation of so small a quantity of sulphur as 0.5 per cent may raise the temperature of the mass 71 deg. it is evident that further attention should be given to sulphur and the rôle it may play in the starting of spontaneous combustion in stored coal.

In 1831 "John Samuel Dawes of Bromford, in the Parish of West Bromwich in the County of Stafford, Ironmaster," was granted a patent, No. 6,207, on the use of pulverized charcoal or any other fuel applicable to the purpose. The specification shows the fuel was to be used in the blast furnace.

## News Of the Industry

### New Temple Anthracite Coal Co. Formed By Merger of Two Independents

Temple and East Bear Ridge Companies Consolidated—Organization Controls Seven Collieries and 40,000,000 Tons of Mineable Coal—Sproul Reticent on Plans

Special to *Coal Age*

Scranton, Pa., Sept. 9.—One of two anthracite company mergers reported in the progress of formation for some time past was effected over the week-end. The Temple Coal Co., of Scranton, and the East Bear Ridge Co., also with offices in Scranton, have consolidated, forming the new Temple Anthracite Coal Co.

For weeks rumors of combinations involving independent operations in the anthracite belt have been discussed in financial circles. Definite information was lacking until last Friday, when authoritative announcement was made. John H. Brooks & Co., of Scranton, members of the New York Stock Exchange, handled the merger.

The new Temple Anthracite Coal Co., through ownership of stocks of subsidiary companies and leases, will now control and operate the following seven hard-coal collieries: Northwest colliery, near Carbondale, with approximately 560 acres of coal land and a breaker having a capacity of 1,000 tons per day; the Lackawanna colliery, about six miles north of Scranton, with 1,080 acres of coal land and a breaker of 1,200 tons capacity; the Sterrick Creek colliery, near Scranton, with 748 acres of coal land and a breaker of 2,000 tons capacity per day; the Mount Lookout colliery, about 10 miles south of Scranton, with 632 acres of coal land and a breaker of 1,500 tons capacity; the Harry E. and the Forty Fort collieries, about 14 miles south of Scranton, with 1,074 acres of coal land and a breaker of 1,000 tons capacity per day, and the East Bear Ridge colliery, at Frackville, with 266 acres of coal land and a breaker having 1,200 tons capacity.

The estimated recoverable coal in these properties is in excess of 40,000,000 tons. Assets of the new company will consist of other mineable coal in various perpetual leaseholds, which at a conservative equity of 20c. a ton for coal in the ground has a value of over \$8,000,000; seven modern breakers with machinery and equipment, all necessary buildings for operation of the plants, eighty-three dwellings, fourteen barns, 3,343 mine cars, 267 mules, 8 horses, 39 electric and 14 steam locomotives, all of which are estimated to have a value in excess of \$4,000,000.

The officers and directors of the new Temple Anthracite Coal Co. are: Chairman of the Board, Thomas R. Brooks, Scranton; President, F. H. Hemelright, Scranton; Vice-President, Seward Button, Wyoming; Secretary and Treasurer, A. M. Bingham, Scranton; Directors, Thomas R. Brooks, F. H. Hemelright, George R. Brooks, G. T. Davis, all of Scranton; S. B. Thorne and B. A. Thompson, both of New York, and James B. Neale, of Pottsville.

Scranton, Pa., Sept. 9.—Former Governor W. C. Sproul, stopping in this city en route to Pike County, would not discuss details in connection with the reported merger of independent anthracite coal companies which he is said to be directing. He admitted that he was interested in the consolidation of a few of the independents in the hard-coal field, expressing the opinion that "the time is ripe for such a move." Details of the proposition, he stated, are under consideration.

### Take Action to Boost Output In Central Pennsylvania

In an effort to put the central Pennsylvania bituminous-coal field in its former high place as a producer of coal, the Association of Bituminous Coal Operators of Central Pennsylvania and the Central Pennsylvania Coal Producers' Association, meeting jointly in Altoona, Pa., on Friday, Sept. 5, adopted a resolution instructing the board of directors and the executive committee of the association "to take such steps as they deem necessary and to perform such acts as may be requisite to restore the central Pennsylvania district to its proper place as a producer of coal."

The members of the associations pledged themselves to support any steps taken in pursuance of the object of this resolution.

Officers of both associations were elected, one group acting for both, as follows: President, B. M. Clark, Indiana; Vice-President, G. Webb Shillingford, Clearfield; Secretary-Treasurer, Charles O'Neill, Altoona; Statistician, W. A. Jones, Altoona; General Counsel, A. M. Liveright,

### Three Railroads Place Big Equipment Orders

The Philadelphia & Reading R.R. is about to purchase 1,000 fifty-ton box cars and 1,000 seventy-ton gondolas, according to an announcement from Philadelphia Sept. 4. This follows closely an announcement by the Pennsylvania R.R. that it had placed an order for 10,000 all-steel box cars.

Details of the cost were withheld, but the steel trade estimates the value of the contract at \$20,000,000. According to an official announcement, the business went to the American Car & Foundry Co., the Standard Steel Car Co., the Pressed Steel Car Co. and the Bethlehem Steel Co.

W. J. Harahan, president of the Chesapeake & Ohio, has announced the closing of a contract with the Richmond (Va.) Car Works, Inc., for equipping 1,000 70-ton hopper-bottom gondola cars with new bodies. The railroad company also has placed with the Inland Steel Co. and the Illinois Steel Co. contracts for 5,000 tons each of steel rails.

Clearfield; Labor Commissioner, John C. Forsyth, Clearfield.

The Central Pennsylvania Bituminous Operators' executive committee includes B. M. Clark, Indiana; Rembrandt Peale, New York and St. Benedict, Pa.; J. R. Caseley, DuBois; S. J. Wills, DuBois; C. B. Maxwell, Morrisdale; H. B. Scott, Philipsburg; Thomas F. Kelly, Coalport; J. William Wetter, Philipsburg; G. Webb Shillingford, Clearfield; Edgar W. Tait, Pittsburgh; William Lamont, Elmora; I. A. Boucher, Beaverdale; Harry Boulton, Philadelphia; S. T. Brown, Indiana, and N. J. Bracken, Johnstown.

Following is the board of directors of the Central Pennsylvania Coal Producers' Association: J. William Wetter, Philipsburg; R. H. Sommerville, Winburne; M. J. Bracken, Johnstown; H. J. Meehan, Johnstown; James H. Allport, Barnesboro; S. J. Wills, DuBois; Edgar W. Tait, Pittsburgh; W. R. Craig, St. Marys; G. Dawson Coleman, Philadelphia; D. T. Price, Windber; Charles A. Owen, Johnstown; Rembrandt Peale, New York; B. M. Clark, Indiana; J. R. Caseley, DuBois; James B. Neale, Minersville; G. Webb Shillingford, Clearfield; W. S. Blaisdell, Punxsutawney; F. B. Kerr, Clearfield; C. B. Maxwell, Morrisdale; Harry Boulton, Philadelphia, and S. T. Brown, Indiana.

## Sir Samuel Kelly Opens Mine In North of Ireland

At Coalisland, County Tyrone, a new mine, says *The Engineer* of London, England, has been opened by a native of Belfast, Sir Samuel Kelly, an owner of mines in Cumberland and of a coasting fleet in the British Isles. The mines are forty-four miles from Belfast, with which they are connected by rail and canal. The coal was struck at 433 ft., previous explorations not having been extended further than 300 ft. It is said that the coal is an excellent bituminous equal to the best Scotch. The shafts are 1,070 ft. deep, 12 ft. in diameter and 62 ft. apart. The seams exposed are 12 in number.

### Seams at Newtownkelly

Depth in Ft.	Name of Seam	Thick- ness Ft. In.	Depth in Ft.	Name of Seam	Thick- ness Ft. In.
433	Kelly	4 9	761	Beltiboy	2 0
476	Crow	4 6	775	Monkey	0 9
542	Annagher	9 6	806	Two-Foot	6
570	Bone	6 3	898	Rock Coal	0 9
625	Shining	2 6	950	Ten-Inch	1 0
691	Bracksville	4 6	986	Ferry Five Foot	2 3

The shafts are fitted with double-decked cages each holding two cars capable of carrying 1,176 lb. apiece. The cages are kept in a vertical plane by six steel-wire guide ropes suspended from the headgear (headframe) and weighted at the bottom by 4½-ton cast-iron "cheeses" (circular weights). Probably 200,000,000 tons of coal are located in the coal basin contiguous. About 200 Scotch miners are at work at present. A town, Newtownkelly, has been erected, 100 houses are already built and 300 more will be added shortly. Each has parlor, kitchenette, scullery, three bedrooms, bath and wash boiler. The rent is 7s. 6d. (\$1.82) weekly. Belfast requires about 1½ million tons and now imports it from across the Irish Sea.

## May Reorganize Addy Co.

The Matthew Addy Co., of Cincinnati, one of the oldest pig iron, coal and coke concerns in the United States, will be reorganized in the event that a proposition submitted to its creditors Aug. 20 is accepted. It is proposed to supplant the Addy company and its branches with a new company, according to the suggestion of Benjamin N. Ford, William W. Hearne and A. Burt Champion, all vice-presidents of the company.

It is proposed to put \$250,000 into the new company, of which \$125,000 will go immediately to pay off some of the creditors' claims. The proposition stipulates that the creditors with claims under \$1,000 be paid in full and the remainder of the \$125,000 prorated among the larger creditors. In addition, the proposal specifies that the new company shall pay off the remainder of the debts at the rate of 1 per cent a month. These payments shall come out of the earnings of the company after it has been functioning six months.

About thirty creditors were represented. Following submission of the proposal the meeting adjourned until Sept. 10, when the creditors will meet again to take final action.

John C. Maben

Former president and one of the organizers of the Sloss-Sheffield Steel & Iron Co., died at Atlantic City, N. J., Sept. 1, at the age of 85. Besides taking an active part in organizing the Sloss Iron & Steel Co. in 1887, and its successor, the Sloss-Sheffield Steel & Iron Co., in 1899, he was one of the organizers and directors of the Richmond-West Point Railway & Warehouse Co., now part of the Southern Ry.

## Will Manufacture Fuel By Trent Process

A. B. Lansberry, operating a large bituminous mine at Clearfield, Pa., is constructing a SuperFuel plant which will use the Trent process and have a capacity of 500 tons per day. The plant will be used to convert his slack pile into SuperFuel as well as to operate on run of mine coal. Mr. Lansberry's plant is the first SuperFuel plant built in the Clearfield district.

Since the present coal depression began Mr. Lansberry has continued to operate his mine and has stored a large quantity of slack for which he has found no market.

M. J. McQuaide, president of the Ben Franklin Coal Co. of West Virginia, announces that the SuperFuel plant which the Pittsburgh Trent Corporation is constructing for him at his Panama mine at Moundsville, W. Va., will be in operation about Nov. 1, 1924. The Panama mine has long been one of the large operations in the Moundsville district, but has practically suspended operations during the present coal depression.

The company which will operate the SuperFuel plant at Moundsville is known as the West Virginia SuperFuel Co., with offices in the Park Building, Pittsburgh, Pa. M. J. McQuaide is president and R. J. Balph is secretary.

Arrangements have been made to market the SuperFuel in Pittsburgh through the purchase of a river frontage for storage, from which the SuperFuel will be distributed to consumers in Pittsburgh. Arrangements also have been made for storage in Cincinnati. The McQuaide interests have been operating a line of steamers and barges on the Ohio for some time and the product will be largely delivered by water.

## Coal Shortage Unlikely Next Winter, Says Report Of Engineers' Committee

Unless there be a strike or suspension at the mines, there should be no coal shortage next winter, the report of the American Engineering Council's coal storage committee has announced as a result of an investigation carried on by 400 engineers in all parts of the country. The report was made public at the council headquarters, 29 West Thirty-ninth Street, New York City, by ex-Governor James Hartness of Vermont, president of the body.

While no shortage is anticipated, the "gorge or diet" tendencies of consumers, coupled with an extremely irregular market, are producing "feast or famine" conditions in the coal industry, the report continues. Runaway prices are said to be caused by the frantic bidding of purchasers against each other, to which some of the operators "are quite willing accessories."

The report insists that, through storage of coal, huge wastes, running into the millions each year, could be averted. There are about 90,000 carload-lot buyers, and to these storage of large quantities of coal is limited. The report adds that:

"The retailer supplies practically all the millions of householders with both anthracite and bituminous coal. He also handles some 30,000,000 tons of bituminous coal for industrial use and for small public utilities. Much of this is dependent on day-to-day deliveries from the yard. The aggregate storage capacity of the bunkers and bins of these small consumers is not known, though it probably runs into millions of tons.

"Storage of a winter's supply by these consumers may, indeed, be impossible, but it does not follow that larger bunker capacity would not be so desirable. If the economic incentive to storage is sufficient, even these small consumers will find means to increase their fuel reserve."

The committee found that, in addition to the retailers, there were about 52,000 consumers throughout the country who bought in carload lots, principally railroads, public utilities and large factories. In such cases the problem of storage becomes an important one, calling for construction of mammoth plants for that purpose. It is one that should be solved, the report urges, if the coal supply is to be stabilized.

After having spent three weeks in Belgium, northern France and in Paris, A. C. Fieldner, chemical engineer, in charge of the Pittsburgh station of the Bureau of Mines, will continue his investigations, with the following schedule: Sept. 7-14, Geneva, Berne and Zurich; Sept. 15-20, Mannheim and Frankfurt; Sept. 21-Oct. 6, Essen, Cologne, Dortmund, Düsseldorf and Geluenkirchen; Oct. 7-14, Berlin; Oct. 15-24, Halle, Dresden, Leipzig, Altenberge; Oct. 25-30, other points in Germany and several points in Holland; Nov. 1-14, Great Britain. Mr. Fieldner will sail for home on Nov. 15.

# British Mining Discloses Methods That May Soon Be Seen in America

Time Near When Thinner and Deeper Seams Must Be Worked Here—  
Difficult Workings, Labor Relations and Safety Ably Handled  
by British—Stone Dusting Universal

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Called to Great Britain by the Power Conference many Americans interested in coal took advantage of their presence in the British Isles to acquire some first-hand knowledge of the conduct of the coal industry there. Most of these observers were men in whom the American weakness of bragging is not pronounced. They looked over the British coal fields with the thought of learning something from their practice which could be applied profitably here. Some of the showy things like bigness, newness or pretentious external appearance of plants in this country cause some Americans to think that we have incorporated in our practice all that is worth while in the production of coal. The observers, however, who are now returning from overseas are not of that type. They attach significance to many of the things they saw. They realize, among other things, that there is an explanation of the fact that the American miner produces nearly four times as much coal per day as does the British miner. Our good fortune in having deposits of rich coal laid down in thick seams accounts in part for this and certain other comparisons which are not as adverse as they seem.

American coal operators, for instance, will find much of profit, some of these observers declare, in a study of the design of British mine workings. They have exhausted the thick and easily accessible seams. They now are forced to grapple with increased physical difficulties. They are winning coal with a profit from 30-in. seams, 24-in. seams, 20-in. seams, and even from seams of less thickness. They are digging coal through shafts that are 3,000 ft. deep. Some operations are carried on under 4,000 ft. of cover. They are working beds of coal which lie between other beds which long since have been removed. They are contending with bad roof and with bad floor and are removing coal that already was badly broken and fractured in its place. Despite these facts, they get an extraction of 90 per cent with a loss of life that is one-half the rate in this country. They operate successfully in mines so gaseous that no powder or electricity may be introduced.

Every coal mine in England now is making stone dusting a regular practice. The cost of dusting has been reduced to the point where it is less than a penny per ton. In one of the mines visited by the Americans, in South Yorkshire, there has been no fatal accident in five years. The property is over 3,000 ft. deep and employs 2,700 men. It is typical of many others. The Americans were amazed at the low

point to which mortality has been reduced. The methods employed in safeguarding workmen are not all directly applicable to the natural and competitive conditions which exist in this country, but their success in promoting safety is regarded as of the greatest significance and deserving of close study by American engineers.

The point is being reached in several of our coal fields where resort must be had to thinner and deeper seams. The development of such properties must be planned at this time along lines that will permit the future recovery of the remaining resources of the property. Many even now could profit from a study of the British practice in mining a series of beds which lie one above the other, so as to obtain the maximum coal at a minimum cost. Much was observed at British mines that would be of particular moment in the operation of certain properties in the Pittsburgh, Pocahontas, eastern Kentucky and Illinois districts.

In the matter of labor relationships the consensus of opinion is that we have much to learn. In certain respects wage disputes and other conditions of employment are handled much more effectively there than here. In Durham and Northumberland particularly the Americans were impressed with the friendly and businesslike methods employed and the wholesome respect the representatives of each group seemed to have for the other. Day-to-day adjustments were being handled with complete absence of friction. The Americans were much interested in their method of evening up the differences occasioned by a bad working place. Every three months in each mine the men draw lots for the working places and shift about so that those who have been working under difficulties have a chance to get a better place during the next quarter. This system, which is known as "caveling," may not be applicable elsewhere, but it is indicative that the inequality of opportunity in working places is recognized.

In Northumberland they seem to have worked out a means of readjusting the piece rate in different seams and in different mines without changing the general level of rates. If the miners in a given mine can show that they are making 5 per cent less than the "county average" they have an argument for an increase which may be taken up before the joint conference. In similar fashion, if the operator believes rates in his mine are out of line with rates in other mines and if he can show that the average earnings elsewhere are 5 per cent higher than his earnings, he has shown cause for the consideration of a reduction and can bring his case before the joint confer-

## Governor Nestos Urges Coal Buying Now

Governor Nestos, of North Dakota, in a recent statement, urged citizens of the state to lay in a coal supply to assist in the rapid movement of North Dakota crops to market, by lightening the burden on the carriers.

"I have been just advised by the Northwest Regional Advisory Board that they have adopted a resolution urging all users of fuel, and especially the institutions that use a great deal of it, to lay in a stock now so as to relieve the railroads in the time of the peak movement of grain and other crops," said the Governor.

"While I realize that the users of lignite coal cannot lay in their supply for the whole year, nevertheless it would be wisdom to lay in supplies, both of lignite and in cases where the other coal is used, of that coal sufficient to last until the beginning of the new year so that in late September, October and November our freight cars may be free to carry our splendid crops to market."

ence. Under this system of bargaining the great inequalities of earnings, such as occur in our anthracite region, are eliminated.

## Union Sued for \$100,000 When Woman Is Fired

Eight labor union locals and over a score of individuals, mostly officers of unions at Hurst and other portions of Williamson County, Illinois, are defendants in a suit for \$100,000 damages filed in the U. S. District Court, at Danville, by Isabel Russell, of Cape Girardeau, Mo.

She alleges she lost her position as manager of the Herrin Supply Co. because she had been blacklisted by the unions and a demand was made on her employers for her dismissal. Mrs. Russell asserts that she was unable to obtain other employment as a result of the blacklist, and was forced to go to another state. The complainant's husband, T. P. Russell, was foreman of the mine-riot grand jury, which returned the indictments in the killings of the non-union miners in the mine-riot cases at Herrin.

## Anthracite Circular Prices For September, 1924

(Gross Ton, F.O.B. Mines)

	Broken	Egg	Stove	Nut	Pc&
Lehigh & Wilkes-Barre.....	\$8.00	\$8.75	\$8.75	\$8.75	\$5.75
Pattison & Bowns.....	8.90	8.90	9.15	8.90	5.50
Phila. & Reading.....	9.15	9.15	9.40	9.15	6.00
Lehigh Valley.....	8.50	8.75	9.05	9.05	5.75
Lackawanna.....	8.00	8.75	8.75	8.75	5.75
Lehigh Coal & Nav.....	9.25	9.25	9.50	9.25	6.00
Del. & Hudson.....	9.00	9.00	9.00	9.00	6.00
Thorne, Neale & Co. (Temple Coal Co.).....	9.20	9.55	9.20	5.75	
M. A. Hanna & Co. ....	8.80	9.15	9.65	9.25	5.75

Prices for steam sizes, as quoted by companies are as follows: Buckwheat No. 1, \$3 @ \$3.15; rice \$2 @ \$2.25; barley, \$1.50; birdseye, \$1.60.

## Further Losses in Union Field Unless Wages Are Equalized, Says O'Neill

"The operators of central Pennsylvania have not at any time asked the United Mine Workers to take a permanent flat wage reduction," said Charles O'Neill, secretary of the Central Pennsylvania Coal Producers Association, in reply to John Brophy's comment on Mr. O'Neill's statement following the meeting of the operators at Altoona, Pa., Aug. 22. "They have pointed out to the United Mine Workers that the way to have central Pennsylvania return to a permanently prosperous basis is by giving it a chance to compete for the markets of the country during the period of liquidation, this being the time Mr. Brophy and other pseudo-economists tell us that the industry will be purged of 200,000 too many men and several thousand excess mines eliminated."

"In order to avoid having all the miners eliminated from the union mines and all the mines abandoned being union mines, the miners will have to make some sacrifices. If it is to be a competitive war between two sections of the industry, all parties in the unionized section of the industry will have to be willing to help make the fight. By courageous leadership this can be accomplished without surrender of one right, equity or price the miners enjoy under the so-called Jacksonville agreement."

### O'Neill Presents Some Facts

Labelled as "facts" the following arguments are advanced in order by Mr. O'Neill:

"(a) Over 200,000,000 tons of the coal accessible to the Eastern markets and competitive with our coal are being produced from 50c. to \$1 per ton lower cost than coal can be produced in our district under the union wage scale.

"(b) The present wage agreement with the United Mine Workers, which fixes our cost, will not expire until April 1, 1927.

"(c) The decline in production of coal in central Pennsylvania will be more rapid under the present differential in labor cost of 50c. to \$1 than it was before the Great War, when the differential in labor cost of coal in the union fields as compared with the non-union fields was but from 10 to 20c. per ton.

"(d) The present policy means that the 200,000 men who must leave the industry will be union miners and the excess mines eliminated will be union mines.

"(e) In 1924 to date the non-union fields of West Virginia have increased their production 11 per cent over the same time in 1923. In this period central Pennsylvania has lost 27 per cent in production.

"(f) The figures quoted by me were correct in every instance. The lame attempt to label unpleasant truths 'Wage-adjustment propaganda' does not change the facts. Facts are stubborn things.

"(g) If the 'prosperity' which we are assured by the miners is almost here, does arrive it will no doubt result

## "Coal Barons" Have No Primrose Path

In analyzing the statistics of income for 1921 compiled by the Bureau of Internal Revenue the National City Bank, among other things, says:

"We have heard much in recent years about the 'coal barons,' and their ability to fix prices to suit themselves. The number of coal-mining companies making returns for 1921 was 3,656, of whom 1,079 reported net incomes aggregating \$82,654,787, upon which they paid taxes aggregating \$15,219,444. The remaining 2,577 coal-mining companies reported losses aggregating \$72,521,815. Subtracting the sum of the federal taxes from the aggregate earnings of the first group, it appears that the net results of the year's operations to the group lacked about \$5,000,000 of equaling the losses of the second group. The coal industry, as a whole, did not get an even break in that year, and when the figures for 1922, 1923 and 1924 are ready for publication it probably will be found that this has been the case also in at least two of these years. So much for the corporations engaged in 'warming the American people.'"

in an increase in wage schedules in the non-union fields. This would help restore proper competitive relations. We are only interested in securing fair competition. This we do not have at the present time."

## Pledge Aid to President in Improving Engineering

President Coolidge received on Sept. 4 a delegation representing the American Association of Engineers, who called to pledge the support of the organization in connection with any effort of the government to improve engineering conditions throughout the country. The delegation was composed of Harold Almert, of Chicago, president of the organization; A. N. Johnson, F. H. Newell, Morris Bien and A. B. McDaniel. They told the President that their association has a membership of 16,000, with chapters in every important center of the population, devoting their energies to the welfare of professional engineers. They explained that the American Association of Engineers differs from the more technical engineering societies in that its first consideration is of the human element. Mr. Coolidge was told that the basic purpose of the association is to make the engineer a broader and more efficient man and to arouse his active interest in public service. They called his attention also to the fact that the association at this time is initiating a national program dealing with fuel conservation, railroad valuation, the proposed department of public works and the classification and compensation of engineers.

## Canada Still Seeks Substitute For U. S. Anthracite

Various efforts made in Canada to obtain a substitute for American anthracite culminated in several plans being suggested at a recent meeting of the Montreal branch of the Engineering Institute of Canada. About a year ago, reports the Coal Division of the U. S. Department of Commerce, the Institute undertook to investigate the chances for procuring a substitute for anthracite in that market, and appointed a commission to do this work.

The committee decided it should confine its activities to the local fuel situation and reported that American anthracite has been almost exclusively used in the Province in the past for domestic purposes but the hardships and inconvenience due to strikes and coal shortages in recent years, and the probability of a gradual decrease in quality and increase in price of this coal in the future, made it advisable and necessary to carry out some educational work, in order to bring to the attention of the public the value of other fuels.

In the winter of 1922-23, says the committee, some Welsh coal was sold for household purposes, largely unscreened, but people had not found this coal satisfactory. Realizing this, the committee took the matter up with the British Trade Commissioner, who circulated the letter through trade journals in England and drew the matter to the attention of coal operators. At the same time local coal dealers were impressed with the advisability of better grading and screening, and the committee promised support in the way of educating the public.

As a result the committee reports increases in the sale and importation of Welsh and Scotch coal with greater care in grading and screening so that it has "given general satisfaction and proved its superiority over American anthracite."

A further increase in the importation of Welsh coal is expected next season, because Welsh operators have formed local connections with the intention of establishing complete unloading and screening plants in Montreal.

It was explained that coke could be obtained from Nova Scotia bituminous coal, but manufactured in Montreal, which would save the consumer money, as the coke would be much cheaper than American coal, with all economic and patriotic sentiments satisfied.

Labor difficulties play an important part both in the Nova Scotia coke industry and in the production of Welsh anthracite. Welsh and Scotch coal may be substituted for American anthracite, coke may be made from Nova Scotia bituminous, and the difficulties which have been encountered in all countries in making peat a suitable and satisfactory substitute for bituminous coal may be overcome, but it does not appear, says the Department of Commerce, as if labor difficulties either in Great Britain or Canada can be overcome any more readily than in the United States to such an extent as to seriously, for a long time at least, cut into the Canadian demand for American coal.

## "Friendly" Receiver for St. Louis Coal Co.

A "friendly" receiver has been appointed for the St. Louis Coal & Iron Co. James Duncan, one of the directors of the company, was named as receiver. The St. Louis Coal & Iron Co. is the successor of the St. Louis Coke & Chemical Co. The plants are located at Granite City, Ill., and comprise eighty Roberts byproduct coke ovens and blast furnaces, which have an output of 180,000 tons of pig iron and 500,000 tons of coke.

The National Enameling & Stamping Co. for years has had a substantial interest in the company, and the balance sheet as of Dec. 21, 1923, showed the National company to have an investment of \$1,900,000 in the St. Louis company, which was represented by bonds and preferred stock.

In 1923 the company suffered financial reverses due to labor troubles and advancing costs of material, and a reorganization committee was named to try to put the company on its feet. The company has outstanding more than \$2,000,000 in common stock, a trifle over \$3,000,000 in preferred stock and \$6,404,000 in bonds.

## Utility Coal Consumption and Power Output Hit Bottom

Electric public-utility plants consumed 2,778,293 net tons of coal during July, according to a report by the U. S. Geological Survey. This compares with 2,691,891 tons consumed in June, according to revised figures. Fuel oil consumed by utility plants in July totaled 1,391,126 barrels, compared with 1,341,426 barrels in June.

The average daily production of electricity by public-utility power plants in July was 148,300,000 kw.-hr., about 2 per cent less than the revised figures for the daily output of the month of June. Average daily output has decreased uniformly each month from April to July.

Returns from the 1923 census of manufactures just compiled by the Department of Commerce show the coal consumption of various industries to have been as follows: Cane-sugar refining, 982,652 tons; card cutting and designing, 2,469 tons; engraving and die sinking, 2,783 tons; grass mats and matting, 6,796 tons; drug grinding, 75,198 tons; theatrical scenery and stage equipment, 240 tons; gold and silver leaf and foil, 767 tons; blacking, stains and dressings, 14,060 tons; lead pipe, bar and sheet lead, 19,799 tons; graphite, 7,071 tons; lithography, 46,341 tons.

A. F. Harper

Recently resigned as superintendent of Woodward Iron Co.'s Mulga mine, Mulga, Ala., to become engineer-superintendent of Flat Top (Ala.) coal mines of the Sloss-Sheffield Steel & Iron Co.

## Our Coal Shipments to South America and Egypt Grow

Comparing United States coal export figures for the fiscal years 1924 and 1923, slight change is noted in exports to Belgium, France, Greece, Canada, Mexico and Cuba. Exports to Germany decreased 204,628 tons. The following are the principal increases in tonnage noted: Italy, 396,971 or 127 per cent; Netherlands, 98,434 or 70 per cent; Panama, 53,543 or 68 per cent; Newfoundland and Labrador, 54,364 or 1,398 per cent; Jamaica, 29,788 or 178 per cent; Dutch West Indies, 34,496 or 113 per cent; French West Indies, 72,289 or 170 per cent; Argentina, 115,657 or 150 per cent; Brazil, 429,494 or 299 per cent; Chile, 42,284 or 362 per cent; Uruguay, 55,659 or 472 per cent; Egypt, 24,384 or 300 per cent; French Africa (other than Algeria and Tunis), 37,920 or none in the fiscal year 1923.

The trend of shipments of American bituminous coal and British coal of all kinds to some of the principal foreign markets in which our coal has competed in the fiscal years ended June 30, 1923 and 1924, is shown in the accompanying table.

Our increased shipments to Italy and South America during the twelve months ended June 30, 1924, are particularly noticeable. Though the total exports during the last half of this period declined, the same thing is true of British exports, though in a less de-

## Is Ford Retailing Coal?

The announcement has gone forth to the 478 Ford agencies in the Northwest that the Ford dock in Duluth has 25,000 tons of coal on hand which will be sold to these dealers in carload lots. They may use it for their own purposes or may sell it in their communities, as they choose. This seems to offset the intimation formerly made that the Ford interests would go into the retail business.

gree. Although the increased trade of this period has been based on extremely low f.o.b. prices, it is possible that any necessary advance in the prices of American export coals will in a measure be compensated by advanced f.o.b. prices of British coals, due to the recent advance in wages of British miners.

Exports of anthracite during the fiscal year just ended amounted to 3,927,846 gross tons, an increase of 194,132 tons, or 5.2 per cent, from the preceding fiscal year. During the six months ended June 30, 1924, anthracite exports totaled 1,755,339 tons, compared with 2,172,507 tons for the preceding six months period, a decrease of 19.6 per cent.

## P. & W. V. to Segregate Coal Holdings

Directors of the Pittsburgh & West Virginia Ry., frequently mentioned as an ultimate participant in the gigantic new "Nickel Plate" group being organized by the Van Sweringens, voted Sept. 8 at a meeting in New York City to segregate their rail properties from their coal holdings, embraced in the Pittsburgh Terminal Coal Co.

It was decided to call the Pittsburgh & West Virginia Railway Co.'s entire issue of preferred shares, \$9,100,000, for redemption, in accordance with the by-laws of the company, and to offer common stockholders the right to purchase, pro rata, the capital stock of the Pittsburgh Terminal Coal Co. now in the railway treasury, amounting to 40,000 shares of preferred stock, par value \$100, and 80,000 shares of common stock, par value \$100, for the total sum of \$4,000,000. This figures that the holder of 100 shares of railway common stock may purchase thirteen shares of the coal company preferred and twenty-six shares of coal company common for \$1,300. It might, furthermore, be stated that dividends on the Pittsburgh Terminal Coal Co. preferred stock have been paid regularly since the date of issue, and in addition thereto dividends on the common have been paid into the treasury from time to time.

It has also been decided, subject to the approval of the Interstate Commerce Commission, to issue \$3,000,000 of 5 per cent equipment trust notes.

The Pittsburgh Terminal Coal Co. owns and operates 10,500 acres of bituminous-coal lands in Pennsylvania, with an estimated unmined reserve of 72,500,000 tons.

## Coal Exports from Great Britain and United States

Country	British Coal			U. S. Bituminous Coal

## New York Retailers Hold Big Convention

The fourteenth annual convention of the New York State Coal Merchants' Association, held at Stamford-in-the-Catskills, Sept. 4-6, was the best attended in the history of the organization. Business sessions were held each morning of the three-day meeting, the afternoons and evenings being devoted to recreation. The following papers were read: "Profitable Facts and Penny-wise Fallacies," E. A. Konzelman, Buffalo, general manager Kon-Wald Engineering Co.; "Buckwheat Coal, and Appliances for its Economical Utilization," C. A. Connell, combustion engineer, Anthracite Economies Co., Philadelphia; "Business Ethics," Samuel B. Crowell, president, National Retail Coal Merchants Association; "Association Work in Chicago," L. W. Ferguson, late president, Chicago Coal Merchants Association; "The Modern Crook—A Menace to the Coal Merchant," F. W. Withey, vice-president, National Surety Co.; "What the Customer Thinks of the Coal Dealer," Robert W. Disque, business manager, *Syracuse Post-Standard*; "Advertising for the Retail Coal Merchant," by John E. Lloyd, Philadelphia, president of William M. Lloyd Co.

The officers of the association were

re-elected, as follows: Charles B. Staats, Albany, president; C. A. Elwood, Rochester, first vice-president; R. J. Wulff, Brooklyn, second vice-president; J. H. Murray, Waverly, third vice-president; J. M. Gaffers, Albany, treasurer; F. A. Eldredge, Auburn, recording secretary; G. W. F. Woodside, Albany, executive secretary.

## New York Banks Give Credit To Aid Ruhr Coal Industry

The Equitable Trust Co., heading a syndicate of ten New York banks, completed arrangements Sept. 8 for a credit of \$5,000,000, to \$10,000,000 for German coal mines. Within these limits the amounts to be extended are indefinite. It depends upon how much the German coal mining trade needs. The advances are designed to facilitate the movement of German coal, either for export or for domestic consumption. The loan is secured partly by coal already in storage, and has the guaranty both of the German coal syndicate and a number of German banks.

While the credit is of the discount type and runs for approximately six months, the German coal mines obtained it on a 6½ per cent basis.

This credit is the latest of a series under negotiation for various trade interests in Germany.

## Union Closes West Kentucky Branch Office

That the United Mine Workers are losing their grip in western Kentucky (District 23) was shown a few days ago, when a branch office of the union at Madisonville, Ky., was closed, due to the large number of union men who had deserted the union in going to work for the St. Bernard properties of the West Kentucky Coal Co., Hart Coal Co. and other companies that are operating non-union.

The stronghold around Central City, within a radius of nearly twenty miles in every direction, is as strong as ever in so far as actual operations are concerned, but the workers do not appear to be backing the union as seriously. On Labor Day a parade, which it was claimed would number 6,000 came out with but 1,002 marchers, by actual count made by operators' agents. A free dinner pulled only 1,200 all told.

Out of Central City as far as Beech Creek in one direction, sixteen miles to Nortonville, and 20 miles toward Louisville, there are practically no operating mines, but down in Hopkins County, around Earlington and Madisonville, the strike has been fairly well broken, and also in Henderson County. In Muhlenburg and Ohio counties things are about as they have been.

(a) Includes 2,328,843 tons of "range" coal, valued at \$20,179,951. (b) Includes culm, No. 4 buckwheat, silt, and run-of-mine-coal. Statistics compiled by H. L. Bennett, U. S. Geological Survey.

# Practical Pointers For Electrical And Mechanical Men

## Blowpipe Renews Mine Machinery

When Equipment Fails Under Stress or Is Damaged by Accident,  
Welding Puts It Again Promptly in Service—Locomotive  
Frames and Pump Easily Repaired

**"S**ORRY, but we have discontinued that pattern." This was the answer to efforts of a mine superintendent attempting to secure a new cast-steel frame for an electric locomotive, which had been in a smash. Not only had the frame been broken, but the electrical equipment was somewhat damaged. It was decided that if a new frame could be obtained at a reasonable cost or the old one repaired it would pay to rebuild the locomotive, otherwise not. So the remark meant that new patterns would have to be made in order to cast a new frame. And the price of this was prohibitive. This is the sort of circumstance that is liable to lead many a good machine to the scrap heap unless it is known that welding makes possible practically

any repair. The mine superintendent in this case was one of those well-informed men, for he knew the casting could be satisfactorily repaired, but had no man available who could handle a job of this size, so a competent welding shop doing business in the neighborhood got the job. There were five breaks on the frames. One end frame was broken through the center and both side frames had their ends broken off. These ends were so badly shattered that new sections were cast for welding to the frame. Preparation of these frames for welding was handled in the usual manner except that they were not preheated. Breaks were chamfered and the castings carefully lined up. Pre-

heating was unnecessary because the breaks were through metal free to expand; furthermore, the material was cast steel. The magnitude of the job readily can be judged by the time required to weld the five breaks—174 hours. Even so, the cost of the repair by welding was only one-twentieth of what a new frame would have cost.

### MINE PUMP REBUILT

The locomotive frame was not the only large piece of mining equipment being handled by the welding shop at the time. The water end of a mine pump had been left to be reclaimed. One of the top outlets had cracked and one of the large end flanges was full of blowholes. Owing to its complexity this casting was preheated. After welding and finishing the casting, the wood lining was replaced. Here again the total cost of repairs was only a fraction of what a new casting would have cost and the delay in obtaining a new one obviated. Both the locomotive and the pump head have been in use some time since they were welded and have given a full measure of service. Without question welding is the most practical as well as the most economical method of making such repairs.

### Welded Sections of Locomotive

Many a mine locomotive bumps along from day to day and causes high maintenance charges because some part of its frame is cracked or out of alignment. Worn parts may be easily welded and refinished so as to fit like new. Old-style frames must be repaired because, in many cases, the patterns have been destroyed or replacements are few and consequently expensive.

#### Reclaimed Pump

This cast-iron water end of a plunger pump was preheated before being repaired. Worn spots, cracks and blow holes were filled, and the pump was again placed in service.

Some coal mining companies are now equipping their shops with welding apparatus which often saves money where large wastes formerly ate prof-

its. Continual progress is being made along these lines at modern mining plants.

*Oxy-Acetylene Tips*

#### Inexpensive Device Removes Water from Steam Line

At coal-mine power plants it often happens that it becomes desirable to extend the steam line, either temporarily or permanently, beyond the terminus originally intended. If satu-

#### Improved Steam Line Drain

rated steam is used, as is usually the case, the longer the line is made the damper will be the steam at the end, whether the line is covered or bare.

The usual method of removing water from steam is by means of an eliminator connected to a trap. Neither of these devices may be available, however, for temporary work, in which case the device shown in the accompanying illustration can be used. Although the results obtained with it may not be comparable with those obtained from an eliminator nevertheless this contrivance made from pipe and fittings, odds and ends, in many instances may save much trouble from water in the steam.

As is well known, steam in passing

through the eliminator is made to turn a sharp corner, usually at fairly high velocity. In other words the steam "plays crack-the-whip" with the globules of water held in suspension by it. The same principle is utilized in the arrangement of piping here shown. Steam coming from the boiler is given a quick turn upward. The water, being many times heavier

#### Barrel on Trolley Track For Filling Cells

Distilled water in the barrel flows through the rubber tubing to a pinch cock at the end. All the cells in the twelve storage-battery locomotives in this mine are quickly filled by this labor-saving device.

volume for volume than the steam, cannot make this sharp turn and strikes the side of the tee, whence it runs down into the drop leg.

From this leg the water may be either conducted to a trap or blown off periodically by hand. The trap works automatically and requires no attention. If the drop leg must be hand-drained it is well to connect a gage glass to its side so that the height of water in it may be visible at all times. The water then need not be eliminated more often than is necessary.

#### Barrel on Trolley Track Used To Fill Battery Cells

The job of putting water into the storage-battery cells used on the locomotives of the Donk Bros. Coal & Coke Co. at Thermal Mine No. 4, near Edwardsville, Ill., is no small undertaking. Twelve battery locomotives are charged in one station at the foot of the shaft.

Some of these locomotives are quite large and consequently are operated from high-capacity batteries which at the end of each day must be carefully inspected, refilled with distilled water and charged.

Both lead and iron-nickel cells are used in these batteries, the total number of cells being about 750. Every night when the locomotives arrive at the charging station each cell is opened and inspected.

To facilitate the work of filling the cells with distilled water an overhead trolley track has been mounted on the roof above the locomotives. A barrel provided with trolley wheels and bracket is suspended from the trolley and a hose with a pinch cock enables the workman quickly to fill any of the cells. All the water used in these batteries is distilled outside the mines in an electrically operated still.

# Production And the Market

## Coal Market Reflects Increasing Strength in Inquiries, Output and Prices

Abiding faith of the coal industry in an autumn revival in business is in process of fulfillment. A touch of cool weather served to inject the needed stimulus to trade, which seems to be gradually but steadily gaining in headway. While buying in many instances continues to be mostly for immediate requirements, consumption is increasing and current needs are mounting. The stockpiles of those foresighted consumers long absent from the market, having made ample preparation for a possible protracted strike last spring, are approaching the vanishing point at a rate that brings additional encouragement to the coal producer. The iron and steel industry continues on the upgrade, operations, output and orders showing a steady gain. Freight-car loadings by the railroads also are climbing at an encouraging rate. Meanwhile the volume of inquiries is increasing to a degree that would indicate that the upturn is not to be evanescent.

### Idle Mines Resume Operations

A number of mines that have been idle in various fields since the depression set in have reopened, many more are preparing to resume and most of those that have been operating on reduced schedules are increasing their working time. Distress coal has ceased to be a market factor in most fields.

Coal Age Index of spot prices of bituminous coal not only regained the point lost last week but advanced a point beyond the figure for the preceding week, standing on Sept. 8 at 166, the corresponding price being \$2.01, compared with 164 and \$1.99 on Aug. 30. This is the highest level reached since June 30.

Activity at Hampton Roads slowed down somewhat last week, dumpings of coal for all accounts for the seven-day period ended Sept. 4 totaling 327,133 net tons, compared with 364,227 tons in the previous week.

Movement of coal up the lakes is heavy, though still far short of the volume of a year ago, as well as of

1921, which was an active season on the lakes. Dumpings during the week ended Sept. 7, according to the Ore & Coal Exchange, were as follows: For cargo, 850,865 net tons; for fuel, 47,228 tons, compared with 871,500 and 44,956 tons respectively the week before.

Production of bituminous coal took another big jump during the last week in August, almost reaching the eight and three-quarter million ton mark. The total output for the week ended Aug. 30, according to the Geological Survey, was 8,773,000 net tons, an increase of 420,000 tons over the preceding week, when 8,313,000 tons was produced, according to revised figures. Anthracite output likewise increased slightly during the

week ended Aug. 30, 1,720,000 net tons having been produced, compared with 1,711,000 tons during the previous week.

A marked improvement is observable in the anthracite market, demand being much stronger and prices notably firmer. Independent quotations in fact have increased in some instances 50c. per ton. Except for a few mines affected by local strikes, all the company collieries are working full time. Stove coal, as usual, heads the list in demand, though a steady call is in evidence for egg and chestnut and pea is not far behind. A slight stiffening in call for steam sizes also has appeared and prices are holding close to the circular.

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Pick-up Runs On

The Sept. 1 pick-up in the Midwest coal business has been running along fairly well. Most of the business, however, is in orders signed up just before the Sept. 1 increase in southern Illinois prices. It is expected to run out about the 15th and be followed by a low period until toward the end of the month, when another rise is expected in demand if not in price. Cool weather around the Lakes and Northwest territory has added its modicum, enabling many retailers to start moving domestic sizes out of their yards. Other business, however, is still slow. Steam from all Midwest mining regions is very sluggish and nut and egg still stand unbilled at almost every mine that is trying to run. Some additional properties opened up early in the month, but these were few in Illinois and fewer still in Indiana, except for mines on the Chicago, Terre Haute & Southeastern which have resumed after a week's strike over miners' trains.

As viewed from the Illinois fields, there is little business except in Franklin and Williamson County lump and egg. All other sizes in those regions are sluggish. Slow but steady increase in business has caused several properties

to prepare for reopening late this month. The increase from two to about three days a week in running time of the average commercial mine is greeted with joy in those communities whose mines actually are operating. Duquoin and Jackson County mines also feel the lump pick-up, but the Standard district still is decidedly in the dumps. The Mt. Olive field is finding a little of the domestic market and continues to move out a reasonable volume of railroad mine run and of contract screenings. There, too, a few more mines are preparing to open up.

### St. Louis Domestic Trade Better

Domestic business is picking up at St. Louis, especially on the higher grades of Illinois coal. There is some movement of anthracite, smokeless and coke, but up to the present there is no activity in Mt. Olive or Standard coals, excepting for apartment houses, which are filling up their bins. Wagonload steam is practically stopped and carload steam is slow. Country domestic demand is fairly good for lump. Other sizes are heavy. Local retail prices have not changed, although the price of Franklin County and Carterville lump advanced 25c., on Sept. 1.

Index	1924			1923
	Sept. 8	Aug. 30	Aug. 25	Sept. 10
Weighted average price.....	166	164	165	205
	\$2.01	\$1.99	\$2.00	\$2.49

This diagram shows the relative, not the actual, prices on four-teen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

### Kentucky Prices Stiffen

Demand for western Kentucky coal has been improving somewhat, and operators have advanced prices about 15 to 20c. a ton on block, lump and egg over the week, but small nut, mine run and screenings show no change. Operators are now asking a peak price of \$2.65 for best 6-in. block coal, with best lump quoted as high as \$2.50; and egg at \$2.25@\$2.35, with some houses asking \$2.50. Nut, which comes in numerous sizes, is \$1.75@\$2.25 according to size; mine run, \$1.40@\$1.85; screenings, \$1.20@\$1.35.

Although several mines in strike-bound western Kentucky have resumed in the past few weeks, the increased production, as well as from new strip mines, has been quite well absorbed, and mines are operating on better schedules. The strike situation within a radius of twenty miles of Central City, headquarters of the district union, gives the operators no encouragement.

Feeling in Louisville coal circles has improved as a result of better demand and stiffening prices. In eastern Kentucky the eastern and northeastern sections are busy on Lake and Central States movement, while the southeastern section is shipping to the South and Southeast. The northern and eastern sections in competition with West Virginia haven't been able to advance prices, but the southeastern section has been forcing prices, and some operators are refusing offers of less than \$2.50@\$2.75 a ton, while a few are reported quoting \$3 on best grades of fine block coal. No differential is being shown in eastern Kentucky between gas and non-gas grades of domestic, but on mine run the gas coal men are holding for around \$1.50@\$1.75, whereas non-gas coal is to be had as low as \$1.25 a ton.

### Northwest Trade Is Slow

The coal trade in the Northwest is dissatisfied with the slowness of buyers. The weather has not been such as to start a drive for anthracite and domestic, and industrial bituminous business has been none too brisk. Movement off the docks is slow. The tendency at Duluth and the Twin Cities is to maintain prices firmly at present levels, however. There is enough business to halt serious undercutting. The Ford flurry seems to have passed, now that the intentions of that concern have been declared. Mr. Ford appears to be moving into retail trade through his dealers only a stock which was on his new dock at the time he bought it. Thirty cargoes of coal reached the Head-of-the-Lakes during the week, including six of anthracite.

The coal trade at Milwaukee nears the season for lower temperatures without change in the unsatisfactory conditions that have prevailed for some time. Consumers of anthracite are not apprehensive as to supply, and consequently are not filling their bins early. A slowness is noted in the soft-coal trade also, due to the fact that industrial establishments are not compelled to force their power plants, and probably also to the general disinclination to purchase until the need of fuel becomes urgent. There was an increase in receipts of anthracite by lake during the latter part of August. The total Milwaukee receipts for the month were 107,685 tons of anthracite and 353,296 tons of bituminous coal, making the season's receipts 497,223 tons of anthracite and 1,314,004 tons of bituminous coal.

### Western Business Not Rushing

While some Kansas City dealers advanced the retail price of Arkansas semi-anthracite 50c. on Sept. 1, others, who had announced their intention of so doing, postponed the move until the middle of the month. There was no advance in wholesale prices of any coal of the South-western district. Demand has improved, but not enough to affect prices, which now run thus: Arkansas semi-anthracite lump, \$5.50@\$7; mine run, \$3.50, and screenings, \$2. Oklahoma lump is \$4.50; nut, \$4; mine run, \$3.25; screenings, \$2. Kansas lump, \$4.50; nut, \$4; mine run, \$3.50; screenings, \$2.50.

The Colorado market shows a slight stimulation both in the sales and production of bituminous coals, but conditions are still abnormally slow. Colorado mines worked on an average of twenty-three hours last week with 40 per cent of the working time lost on account of "no market." A slight advance in the prices from southern Colorado fields became effective Sept. 1. Walsenburg and Canon City lump, nut and slack are \$5, \$4.25 and \$3.50 respectively, Trinidad lump is \$4 and Crested Butte high-grade anthracite \$7@\$8.75.

In Utah business is slowing up a little following a spurt caused by the rising market. Prices, however, cannot be said to be settled. Mines are working less than three days a week now. Industrial requirements for this time of the year are normal. An interesting development in Utah retail circles is the increasing demand for domestic lump, a 3x8-in. size. H. F. Fernstrom, president of the retail coal dealers' association, said it was gaining on straight lump. The price usually is 50c. a ton less than straight lump.

### Business Quickens in Ohio Markets

The quickening pulse to business at Cincinnati seems to hold. Lake buyers are more active and not so much inclined to haggle over prices. Domestic buyers also are awakening, but the most favorable sign is word from the Norfolk & Western that the supply of gondolas being set out at the mines had dwindled to a 25 per cent reduction and on the Louisville & Nashville it was 10 per cent below that of the preceding week. Movement through the gateways increased 1,255 loads last week; of the 11,521 cars, 2,013 were destined for the lakes. West Virginia coals sell a shade under Kentucky offerings. There has been little change in the smokeless market, but orders and inquiries are increasing.

A better tone is developing at Columbus, domestic demand being the best feature. Preference is shown for Pocahontas, smokeless and splints. A fair tonnage from the southern Ohio field is moving. Owing to the restriction in lump production there is a growing scarcity in screenings and small advances in the small sizes have been reported.

Steam trade is slow. Railroads are taking a fair tonnage while public utilities are good buyers. School coal is moving in considerable quantities. In the southern field the output is between 18 and 20 per cent and is still going up.

The Cleveland market is not especially keen, but with the noticeable pick-up in general business, buying for current requirements has become more widespread, hence the situation has afforded a stimulant to bring about enlarged operations as compared with the summer months. Even so, there are no reports of additional mines opening up, but many mines which have been operating have increased their output, due to the improved situation. The railroads continue to report increase in traffic, and many feel that the roads will soon be taking more coal to safeguard against weather emergencies and also to provide for their heavier requirements during the winter season.

### Gradual Gain in Pittsburgh Market

The gradual trend to heavier output in the Pittsburgh district continues and the spot market shows increased activity. Prices are unchanged except that steam slack is up about 10c. and gas slack about 5c. Movement of domestic coal continues to increase week by week but is still rather light. There is less shading than 30 days ago, the shading now on domestic 14-in. lump rarely going below \$2.50, while \$2.75 is the objective of leading operators as a minimum, it being felt that the market ought to be \$2.75@\$3, according to quality.

The feeling at Buffalo is better, the trade expecting general business to pick up soon and carry coal with it. It looks as if certain sorts of soft coal would soon be put into the regular anthracite trade, opening a new market for all bituminous. Improvement in slack is reported and some shippers have advanced prices slightly. Quotations are \$2.25@\$2.50 for Yougiogheny gas lump, \$2@\$2.25 for Pittsburgh and No. 8 steam lump, \$1.75@\$2 for all mine run and \$1.10@\$1.30 for slack.

### Atlantic Markets Improving Gradually

A gradual but steady improvement is apparent at New York. Inquiries are increasing and large consumers are more in evidence. The biggest improvement is noticeable in the line trade, the situation at tidewater continuing dull but not inactive. There was a spurt during the middle of the week due to a couple of days of cool weather but the activity, while not so pronounced, continued throughout the six days. "Sold-up" is what some producers of high-volatile coals say when asked about September business and the better grades of low-volatile coals also are ordered well ahead. The improvement has not yet been sufficient to affect prices.

A slight betterment is noted at Philadelphia, the bulk of the business consisting of seasonal buying by small consumers. Spot prices are holding firm and very little coal is to be had at sacrifice prices. At the piers, business is so light that there is very little coal standing. The only coal in active demand is slack, and this continues short at times.

Not only is the domestic market at Baltimore very flat and prices low but the export situation continues extremely unsatisfactory. There are many rumors of coming improvement in local industrial sales and in export charters, but much of the prospective business seems contingent upon other developments. Only one manifest of clearance of a coal-carrying ship has been filed so far this month.

Gradual betterment is shown in inquiry and bookings at

Birmingham. Movement to the ports for bunker and export trade shows no improvement. The wholesale market is rather sluggish. Steam prices are stationary, domestic advancing to the September schedules on the medium and better grades, which are quoted: Big Seam lump, \$3@\$3.25; Carbon Hill, \$3.35; Cahaba, \$4.75@\$6; Corona, \$4; Black Creek, \$5@\$5.25; Montevallo, \$6@\$6.50 f.o.b. mines. Operating conditions are unchanged, output for the week of Aug. 23 being 325,000 tons.

### Anthracite Shows Cool-Weather Stimulus

Considerable improvement is noted in the hard-coal trade at New York over last week. Demand is stronger and quotations for independent coals increased as much as 50c. A few days of cool weather stimulated the trade to such an extent that some of the smaller independent operators withdrew their prices temporarily. September price lists of the larger producing companies as well as the larger independents for the larger domestic coals show increases ranging from 10c. to 15c. The prices for pea coal and the smaller sizes were not changed. Stove coal continues to top the list in point of demand but there is a steady call for egg and chestnut, while pea coal does not lag. Steam coals also are in better demand and No. 1 buckwheat, which has been the slowest to move for several weeks past, is much stronger. Rice and barley hold up, the better grades of the latter size bringing full circular price.

The Philadelphia market is getting a fair amount of trade. All company collieries are now making full time, except a few affected by local strikes. The demand for stove still holds up and at times appears to have grown stronger. The independent shippers, however, insist on a proportion of nut and pea to get stove, while the companies also are asking for balanced orders. Demand is so light that prices have not been increased. The steam trade still lags.

Prices at Baltimore have been advanced about 50c. above those for July and August, except for pea and buckwheat. Purchasers continue slow in ordering, despite a recent spurt to take advantage of August prices.

Marked improvement is reported at Buffalo. With autumn here the consumer is beginning to be interested in coal. Many empty bins are to be filled, for summer buying was so light that a spurt to catch up is due soon.

### Coke Price Recedes Slightly

The spot furnace-coke market at Connellsville has partly lost its advance of 10c. reported a week ago. In the past week there has been some coke offered at \$3 for spot or prompt shipment, and it is rumored that a September tonnage was recently offered at this figure. However, it seems \$3.10 has been paid occasionally and in one exceptional instance, in a sale not to a blast furnace, \$3.15 was paid. The market is quotable at \$3@\$3.10 against \$3.10 a week ago and \$3 for several weeks preceding. Foundry coke continues dull but the market range is unaltered at \$4@\$4.50. The *Courier* reports coke production in the Connellsville and Lower Connellsville region in the week ended Aug. 30 at 17,900 tons by the furnace ovens, a decrease of 1,300 tons, and 32,570 tons by the merchant ovens, an increase of 1,290 tons, making a total of 50,470 tons, a decrease of 10 tons.

## Foreign Market And Export News

### British Market Stronger but Irregular; Output Still Climbing

The south Wales coal market is strong, shipments are heavier and many vessels are awaiting berths, but supplies are curtailed and the general situation is unsatisfactory. Orders are unevenly distributed and prices are irregular. There is little likelihood of idle mines resuming operations at an early date.

The Continental demand is weaker, causing mine owners to feel dubious as to the effect of the Dawes plan. The Miners Federation of Great Britain is against the plan, fearing depression in the industry from reparation payments in coal. Coal owners are less pessimistic and are awaiting the usual autumn upturn, but there is no spirit of confidence throughout the industry. Newcastle prices are a matter of bargaining according to berths. Freights from Wales to west Italy are 8s. 6d. All rates are weak on account of the excess tonnage offering.

The output of the British collieries during the week ended Aug. 23, a cable to *Coal Age* states, was 5,279,000 tons, according to the official reports. This compares with 5,193,000 tons produced during the week ended Aug. 16.

#### French Coal Market Quiet; New Business Scarce

Calm prevails in the French market, little new business being in sight. The output of industrial coals from the Nord and Pas-de-Calais mines sells easily and no appreciable quantities are put in stock, even of dry duffs, which are in least demand.

The strike in the Mons coal basin is expected to increase the sales of the neighboring French coal fields, though its effect probably will be limited. Efforts are being made by the French collieries to stimulate buying in the region of Rouen. In the North, the sugar-making plants are replenishing their coal supplies, which will be fully covered soon.

In house coals the current of orders is sufficient to absorb production.

The rolling-stock situation is satisfactory and freight has been lowered by 1 f. to 19 f., Béthune-Paris.

Deliveries of indemnity fuels to France and Luxemburg for the first eighteen days of August were 179,800 tons of coal, 173,200 tons of coke, and 8,000 tons of lignite briquets.

Deliveries of coke to the O.R.C.A. continue to be light. During the first twenty-six days of Aug. only 237,172 tons was received.

The strike of Belgian miners in the district of Borinage continues, recent reports being to the effect that ministerial intervention might lead to a meeting of conciliation between employers and miners. It is feared, however that the strike may extend to other Belgian fields.

#### Hampton Roads Market Quiet; Prices Stiffen

The market at Hampton Roads is quiet, with a slight stiffening in prices, due more to a somewhat depleted surplus rather than to any extra demand. Business in all lines is holding its own with a few scattered cargoes for Brazil and Italy providing the only activity in foreign trade.

Coastwise trade has not picked up to any great extent, although a few cargoes have been moving North. Bunkers remain fair with a slight increase in general shipping having a tendency to increase business in this channel.

## News Items From Field and Trade

### ALABAMA

The Corona Coal Co. is making preparations to open up some new mines at Mount Valley, near Oakman. A new railroad is to be constructed to the openings.

The Bankhead Coal Co. is constructing a tippie at its new openings near Jasper, Walker County, and it is stated will be in position to produce coal from these mines by the middle of October.

An increase of \$775,000 has been made in the capital stock of the Pratt Fuel Corporation, making the capitalization \$1,000,000. This company, of which Walter Moore, of Birmingham, is president, by reason of the taking over of numerous smaller coal mining operations, principally in the Walker County field, is now one of the largest commercial and domestic producers in Alabama.

During 1923 Alabama's coal production was 20,919,303 tons from 208 mines, an increase of 2,161,622 tons over 1922, according to the official report of C. H. Nesbitt, state mining inspector, made to Governor Brandon. A similar increase in coke output also is shown. In 1923 4,689,641 tons of coke was produced, as against 3,760,064 tons in 1922, an increase of 919,577 tons. Inspector Nesbitt declares that the beehive oven is fast disappearing in Alabama, being replaced by the byproduct type. In 1923 168 ovens were erected in Alabama and all were of the byproduct type. Mr. Nesbitt says that Alabama is increasing its production of coke every year. Last year 6,895,294 tons of coal was burned to produce 4,698,641 tons of coke.

### ARKANSAS

Coal Mines Nos. 2 and 6 operated by the Western Coal & Mining Co., near Altus have been closed indefinitely.

E. W. Hogan, superintendent of the Bernice anthracite mines, announces that mine No. 3 will be opened for operation soon. No. 3 is a slope mine, but it has the same vein and quality of coal as the original Bernice anthracite. An undercutter and other modern machinery will be used and the coal will be hauled by a narrow-gauge railroad, which is completed, to the tippie at mine No. 2 for crushing and sizing. About 20 men will be employed and the force will be increased as the working space becomes larger.

### CALIFORNIA

The Darling and Morris Brothers, of Kennedy Flat, have opened up a small coal mine near Buena Vista, in Amador County, 40 miles west of Sacramento. They expect to produce about 50 tons a day. This is an operation which was worked many years ago for awhile.

### COLORADO

During the month of July Colorado mines produced 616,186 tons of coal. This is a decrease of 73,068 tons as compared with the corresponding month last year. The total number of men employed in and about the mines in July was 12,317.

### IDAHO

H. F. Samuels, who forced the Oregon Short Line to supply rail service on the discontinued branch line from Tetonia Junction to his reopened Brown Bear mines in the Teton basin, has won another battle with the road. He has obtained from the state Public Utilities Commission an order cutting 10 to 20 per cent from the rates on coal which the road fixed to Idaho points when the mines began producing, during the summer.

### ILLINOIS

The McLean County Coal Co. has opened its Bloomington mine, which had been closed since last April.

A new wagon mine has been opened on the farm of E. I. Blevins, in the vicinity of Galesburg.

Coal has been found on the Fred Wallbaum farm, just north of the city limits of Ashland. The vein is 4 ft. thick and has a substantial slate and sandstone roof. The vein was struck at about 200 ft., but drilling will be continued.

The Peabody Coal Co., of Chicago, has bought outright the mines of the Springfield District Coal Mining Co. in and around Springfield. To do this an additional \$1,000,000 of Peabody stock was issued, raising the total from \$8,000,000 to \$9,000,000, and the mines were paid for by transferring Peabody stock to the estate of the late F. S. Peabody, which owned the Springfield District Coal Mining Co. The Peabody Coal Co. has been operating the mines and selling the coal ever since the formation of the Springfield company.

Frank Farrington, state union president, comes out in a public statement

denying a news story printed in the *Illinois Miner* to the effect that there are 2,000 non-union miners working in the small mines of the Fulton-Peoria district, and that the 2,000 are causing great union anxiety. He said that the state coal report of 1923 showed only 383 men working in the wagon mines of Peoria County and declares that everything but wagon mines has long been solidly organized and still is. Therefore he denies flatly that there are 2,000 non-union men mining coal there. He admits many of the little wagon operations are not organized but that steady effort is being made to get them into line.

### INDIANA

Two Indiana coal companies are trying to collect \$160,000 from the Southern Ry. because of alleged discrimination against them in the distribution of cars between September, 1922, and March, 1923. The two companies are the J. I. Wooley Coal Co. and the Warwick Coal Co., both of Evansville. They filed their complaint with the State Public Service Commission.

A number of mines in the Terre Haute district have reopened within the last fortnight. The Bardyke mine, the property of the Fort Harrison Mining Co., has reopened with 400 men employed. The Pine Ridge mine, belonging to the Binkley Coal Co., also has begun operations with 300 men employed. The Pine Ridge mine is near the Bardyke mine, in the vicinity of New Goshen. The Bardyke mine has been closed for about eight weeks for extensive repairs. With the reopening of these two mines, more than twelve mines in the Terre Haute vicinity have been reopened, re-employing more than 1,200 miners.

### KENTUCKY

The Gatliff Coal Co., of Williamsburg, which recently increased its capital stock to \$375,000, has 3,000 acres of coal land under development, and will have daily output of 15,000 tons.

It was reported from Frankfort on Aug. 22 that Thomas P. Middleton, of the "blue sky" department, State Banking Commission, had authorized the Clay County Coal Co. to sell \$75,000 worth of bonds in Kentucky.

The Mayking Coal Co. has been bought by the Imperial Elkhorn Coal Co., of Detroit, Mich., at a price not made public. The capacity of the mine at Mayking has been only 10 cars a

day but the new owners expect to increase this.

## MISSOURI

Supply Commissioner Gus Oetting of St. Louis, has let contracts for coal to be used in city institutions, municipal buildings and the water works during 1924-25 totaling approximately 126,000 tons. The Lake & Export Sales Corporation was awarded the contract for water works coal at \$2.75 per ton delivered on screenings from its mine at Marion, Ill. Other contracts let were: City Hall, wagon delivery, to Berry-Bergs Coal Co., \$3.40 per ton; City Hospital, washed No. 4 coal, Union Fuel Co., \$4.01; Court House and City Infirmary, mine-run coal, Berry-Bergs Coal Co., \$3.73; City Hospital No. 2, Inland Valley Coal Co., \$3.68, and for other buildings and institutions, Union Fuel Co., \$4.06.

## MONTANA

The new Northern Pacific Ry. strip mine at Coalstrip, 40 miles south of Forsyth, began loading coal Sept. 1 and may soon attain an output of 50,000 tons a month. The coal lies under cover varying from 35 to 75 ft.

The Gilbert-Crawford Coal Co., with a mine near Roundup, has been reorganized after a bitter struggle by the officers to retain control. Walter Gilbert and Charles A. Crawford, president and secretary, have withdrawn. The property has been taken over by a concern known as the M & M Coal Co., which has as its officers Fred Buck of Helena, president; Ben Deinard, of Minneapolis, Minn., vice-president, and Henry Unschuld, of Minneapolis, secretary-treasurer. The directorate consists of the three officers and Percy Gaw, of Helena, and David Phillips, of Minneapolis. Headquarters will be in Helena. A change of capitalization from \$100,000 to \$500,000 was made.

## OHIO

The New York Coal Co.'s mine, No. 26, at Nelsonville, resumed operation Aug. 29 after a long period of idleness. More than a hundred men are at work.

Jerome Watson, chief inspector of mines of Ohio, and six deputies have started an inspection of the Blue Rock Mine, in Belmont County, which was flooded in 1913 and abandoned at that time. The workings have been filled

with blackdamp and deadly gases. The inspection will be made with a view of opening the mine after the necessary repairs are made. The chief inspector and his deputies also will inspect the Lincoln Mine of the Lorain Coal & Dock Co., also in Belmont County, which was sealed Aug. 22 because of a fire. If this is found to be extinguished the mine will be opened and repairs will be made by the owner. The same inspectors have arranged to inspect the Doanville mine at Doanville, Hocking County, which was sealed in December, 1920, following a gas explosion. This will be thoroughly explored and if conditions warrant it also will be opened.

## OKLAHOMA

There has been an increase in the Henryetta district coal output. The Crowe Coal Co., having obtained the Frisco R.R. contract, has for some time been loading 400 tons per day at its Whitehead mine. Other mines nearby also are reopening.

The Kalin-Inla mine, near Wilburton, which was raided by a band of men on July 18, and a number of non-union workers forced to quit work in the shaft, resumed operations Aug. 26 under a heavy guard of state troops and state police. Approximately fifty men reported for duty and the full crew of 150 is expected to be at work in a few days. Eight coal mines now are operating in Latimer County under open-shop conditions.

## PENNSYLVANIA

H. B. Douglas, assistant to F. E. Herriman, president of the Clearfield Bituminous Coal Corporation, with headquarters at Indiana, Pa., has resigned after eleven years service with the corporation, and the position has been abolished.

Cranberry local 1434, of the United Mine Workers, Hazleton, is making an effort to have Senator LaFollette, independent candidate for President, address the members on a date to suit his convenience.

As a consequence of the lull in the hard-coal market 417,000 tons of anthracite is now stored in plants of the Pennsylvania Coal Co. and the Lehigh Valley Coal Co. in the Pittston field. At the present time the storage plant of the Lehigh Valley company at Ransom, Pa. contains 122,000 tons of pea coal alone. The Ransom plant can han-

dle 360,000 tons. An average of 10,000 tons has been dumped there for the past four or five weeks. The Pennsylvania company is storing most of its coal at Coaldale. At the present time it has 200,000 tons there. At the Dunmore storage plant of the same company 80,000 tons is stored while 15,000 tons is to be found at No. 9 mine in Pittston. The Glen Alden company also is storing thousands of tons of anthracite.

Joseph J. Walsh, of Wilkes-Barre, state chief of the Bureau of Mines, has decided to open a new file in the state offices in promotion of mine safety work. The new file will carry the records of the work done in all coal-company operations in the anthracite field in first-aid work. Mr. Walsh told the officials of the Hazle Brook Coal Co. at the first-aid outing of that corporation at Hazle Park, Hazleton, that he would open the new file at once.

The property of the Schuylkill Valley Coal Co., which operation has been suspended for months, has been sold for \$184,100 to the Randolph Coal Co., a Delaware concern recently organized for the purpose of bidding in this property and operating it.

The Lincoln Gas Coal Co., of Pittsburgh, has closed down its mine at Lincoln Hill, in Washington County, about a mile and a half from Washington, in order to build a new steel tippie and a new fan. The new tippie will be thoroughly modern, with shaking screens, picking tables and loading booms. The installation probably will be completed in six weeks.

The Orient Mine, in the Connellsville region, recently acquired by the Hillman Coal & Coke Co., of Pittsburgh, at the sheriff's sale of the American Coke Corporation properties, has resumed coal shipments, after being idle for several months. The Buckeye Coal Co., subsidiary of the Youngstown Sheet & Tube Company, has started up the Brier Hill mine, which had been idle for about a year.

One of the largest contracts for coal from central Pennsylvania in years was closed on Sept. 2, when John C. Cosgrove, of Cosgrove & Co., closed with the Staten Island Edison Corporation for 700,000 tons over a period of five years. The Edison plant was recently purchased by new interests and will be greatly enlarged. The Baltimore & Ohio R.R. is one of the largest consumers of Staten Island current, much of which will be used in the proposed electrification plans for the Staten Island division of that road.

Steps have been taken by the Cosgrove-Meehan Coal Corporation at its Thermal mine No. 10, at Foustwell, Somerset County, to put on the market for domestic use three sizes of bituminous coal, lump, egg and slack, to compete with anthracite. A Marcus shaker screen is being installed and steam shovels are at work and the new equipment will be in operation within a few weeks. Three cars may be loaded at the same time with the various grades of coal.

Typical Wyoming Coal Tippie with Characteristic Surroundings

This is at a Union Pacific mine, Winton, Wyo., a mine where adobe dusting by hand started four years ago at a time when only two or three other mines in the country were trying to reduce coal-dust explosion dangers by spreading inert dust.

## TENNESSEE

The Cambria Coal Mining Co., Briceville, of which H. M. Stokes is superintendent and general manager, has acquired the properties and equipment of the Cross Mountain Coal Co., which includes 12,000 acres of undeveloped coal land, about 200 miners' houses, three commissaries, office building and equipment.

## TEXAS

The Texas Pacific Coal & Oil Co. reports for the quarter ended June 30, 1924, net income of \$686,254, after expenses, but before depreciation and depletion, equal to 81c. a share (\$10 par value) on the \$8,448,048 capital stock, compared with net income of \$581,604, or 69c. a share, in the preceding quarter. Income account for six months ended June 30, 1924, showed net income of \$1,267,858, before depreciation and depletions, or \$1.50 a share, compared with net income of \$1,759,014, or \$2.08 a share in the corresponding period of 1923.

## UTAH

H. H. Calvin, former sales manager for the United States Fuel Co. and the Utah Coal Sales Agency at Salt Lake City, has been made special sales representative of the company. A. K. Bell is now general sales manager.

Dr. A. L. Murray, surgeon for the U. S. Bureau of Mines, with headquarters in Salt Lake City, has been assigned to make an inspection and instruction tour of all mine rescue cars and stations throughout the United States.

L. F. Rains, president of the Carbon Fuel Co., Salt Lake City, is chairman of the committee in charge of that city's Defense Day plans.

Beginning Sept. 1 all coal moved from mine yards in Utah to distributing points will come under demurrage rules after 24 hours' free time. Also, in the allotment of cars loads will count the same as empties. This, it is stated, will be the first time demurrage rules have been applied in this state.

## WASHINGTON

The Koltop Coal Co., Mt. Vernon, has increased its capital stock from \$95,000 to \$395,000.

Tax valuations have been reduced in Tacoma on the properties of the Wilkeson Coal & Coke Co. by 25 per cent and of the Carbon Hill Coal Co. from \$341,420 to \$245,000. These reductions were made in response to the pleas of the companies that they have not been able to make any money.

The Lisco mine, at Renton Junction, shut down since June 1 for repairs, has resumed operations with much new equipment installed, including an electric hoist, shaker screens and a washing plant.

In the western Washington mine-rescue and first-aid meet, Aug. 9, the Bellingham team won first place. Newcastle second, Carbonado third and

Black Diamond fourth. The first-aid contest was won by Newcastle with Burnett second and Black Diamond third.

Mine No. 3 of the Northwest Improvement Co., at Ronald, near Roslyn, has shut down indefinitely, throwing 325 men out of work. There is no immediate plan of reopening until the coal market improves.

## WEST VIRGINIA

The Tunnelton Freeport Coal Co., operating at Blaser, near Tunnelton, in which Cumberland people are extensively interested, will resume operations within a short time.

The purchase of 800 acres of Pittsburgh coal in Cass district of Monongalia County, by W. K. Hatfield, of Morgantown, has been confirmed by Mr. Hatfield, but he said that he was "acting for other interests whose identity he could not disclose now." The consideration involved, it is reported, is about \$400,000.

In order to avoid causing an outbreak such as occurred in the Mingo field, the operators in the Kanawha field, who had determined to evict those tenants who had refused to return to work, have reconsidered their decision at the instance of Governor Morgan and will institute suits and obtain judgment for possession, costs and rent.

The Allied Coal Co. has purchased a complete mining plant and 79.56 acres of coal in Clay district of Harrison County. The purchase covers the mining equipment on the premises and all the mining rights. The property was sold by Chester G. Shinn, C. M. Tarleton, Mary C. Tarleton, L. A. Riggs, Tusca Morris, Harriet B. Morris, Harry B. Crane, Edna D. Crane, Boyd S. Fleming and Eva B. Fleming, all of Fairmont.

J. O. Caldwell, secretary of the Northern West Virginia Coal Operators Association, has severed his connection with that organization to become identified with the traffic department of the various Hutchinson coal companies including the Hutchinson Coal Co., Hutchinson Island Creek Coal Co., Logan Mining Co., and the Rich Creek Coal Co. Mr. Caldwell became chief clerk of the Northern West Virginia Association in August, 1920, and in February, 1922, was made secretary of the association after George S. Brackett had been made executive vice-president.

One of the largest single orders for mine cars ever given by a West Virginia mining company was placed recently by the American Coal Co., having operations on the Norfolk & Western RR. in the Tug River and Pocahontas districts, the order calling for \$110,000 worth of new cars for immediate delivery. All of the cars will be of the most modern type now in use.

Eight miles of concrete roads, representing an expenditure totaling \$650,000, have been formally presented to the County of Logan by the Island Creek Coal Co., of Holden. The Island Creek company purchased the right of

way, graded and paved the roads at its own expense and without any contribution by the county. The roads are in three sections—the Trace Fork, Whitman Creek and Coperas sections.

Fire believed to have been of incendiary origin partly destroyed the tippie of the Arnettville plant of the Fort Grand Coal Co. late in August causing a loss estimated at about \$20,000 and suspension of operations. The mine, which is located on the Indian Creek & Northern R.R., has been operating open shop and paying the 1917 wage scale for several years. The mine has been producing about 500 tons a day, much of which is for railroad fuel purposes. The county court of Morongalia County has indicated that it will offer a reward in addition to that offered by the coal company for the capture of the person or persons implicated.

## CANADA

Control of the lignite plant at Bienfait, Sask., is now in the hands of the Saskatchewan government, which is negotiating with one or two firms to take over the plant and operate it as a commercial utility, according to an announcement made at Regina, Sask., by J. C. Gardiner, Minister in charge of industries, who says that the plant has served its purpose in demonstrating the possibility of making briquets from carbonized lignite.

The plant of the Phenix Briquette & Coal Fuel Co., Ltd., has been sold under chattel mortgage in Toronto for \$6,000. W. T. Pember, president of the company, has taken over the plant on a fifteen-year lease from the Toronto Harbor Commission. The total liabilities of the company are \$32,000.

Sir Thomas Tait, president of the Grand Lake Coal & Ry. Co., has been elected a vice-president of the Detroit United Rys. He has been identified with the Canadian Pacific Railway for many years and was one of those instrumental in developing the Grand Lake bituminous coal properties. Sir Thomas headed the company that built the railroad line from Chipman to Fredericton. Previously there had been no railway connections with Minto, which is the chief Grand Lake mining center. The line is about 45 miles long.

At the annual general meeting of the Crow's Nest Pass Coal Co., held at Fernie, B. C., recently, the following officers were elected: President and general manager, W. R. Wilson; first vice-president, H. B. McGiverin; second vice-president, A. H. McNeill; secretary, J. S. Irvine; treasurer, A. A. Klauer; and Comptroller, G. H. Hess. The report for 1923 was tabled. During the year the company produced 775,366 tons of coal and 65,990 tons of coke and made an operating profit of \$471,679 from coal mining and \$61,497 from timber and other sources, enabling the payment of four quarterly dividends of 1½ per cent, aggregating \$372,690, and leaving a credit at the profit and loss account of \$14,276, at the end of the year.

## New Companies

The **Continent Coal Co.** has been incorporated at Birmingham, Ala., by T. S. Abemathy, J. M. Donaldson and G. G. Tait.

The **R. L. Brown Coal Co.**, Middlesboro, Ky., capital \$20,000, has been chartered by R. L., C. O. and L. I. Brown, all of that city.

The **Jennie Wilson Coal Co.**, Owensboro, Ky., in the western Kentucky district, has been chartered with a capital of \$10,000, by Jennie Wilson, Russell Wilson Land George S. Wilson.

The **Weissenborn Coal Co.** has been incorporated in St. Louis, Mo., with a capital stock of \$60,000, by J. E. Weissenborn, Rosalia Weissenborn and S. A. Weissenborn, 3632 Hartford St.

The **San Bois Coal Mining Co.** has been incorporated in McCurtain, Okla., by G. W. Shields, McCurtain; Earl Cobb, Amarillo, Tex., and L. E. Turner, 517 N. 21st St., Fort Smith, Ark.

The **Wayne Coal & Mining Co.** has been incorporated in Tulsa, Okla., with a capital stock of \$50,000, by R. D. Leydig, Edmond Boydston, Chas. A. Holden and others.

The **Hatfield Coal Co.** has been incorporated in Covington, Ky., with a capital stock of \$25,000, by J. T. Hatfield, Chas. A. Hunt and M. H. McLean.

The **Sharon Pond Creek Co.** has been incorporated in Sharondale, Ky., with a capital of \$100,000, to develop coal land, by Wm. York, A. B. York and others.

The **Mammoth Coal Mining Co.**, 1519 American Trust Bldg., Birmingham, has been organized with C. Cooper, president, and J. M. Donaldson, secretary and treasurer. Eighty acres of coal land is under development, with a possible daily output of 200 tons.

The **Solar Coal Co.**, of Freeburg, Ill., has been capitalized at \$180,000 by John White, W. C. Wolf, Robert White, Samuel White and John Mackie.

The **Pennsylvania Coal Co. of Canada, Ltd.**, with headquarters at Toronto, has been granted Ontario incorporation with power to carry on business as coal operators. The authorized capital is \$100,000.

**Prudence Coal Co., Inc.**, Brooklyn, has been organized with \$150,000 capital to manufacture coke and byproducts. Henry Casali, New York City, Constantine Bergamini, Brooklyn, and Harry Aronoff, Brooklyn, are directors and subscribers. A. H. Kurland, 50 Court St., Brooklyn, is attorney for the corporation.

The **Manufacturers Gas Coal Co.**, capitalized at \$50,000, has been organized to operate in Brooke County, West Virginia. Headquarters of the company are to be at Wellsburg. Among those identified with the new company are J. J. Arnold, Washington, Pa.; John W. Conwell, Pittsburgh; W. H. Conaway, Fairmont; E. E. Carter, Wellsburg, W. Va. One of the incorporators, W. H. Conaway, has been attorney for the Josiah Thompson interests in West Virginia for some time.

The **Diamond Coal Co.** has been organized in Provo, Utah, with a capital of \$100,000, fully paid. The company will develop property in American Fork Canyon, Utah County. According to the promoters, the company's property in the canyon has a vein showing at least 6 ft. thick, with a fair promise of an increase as the tunnel is driven into the mountain. Incorporators are: T. E. Nicolodimos, John Blathran, Daniel Odysseis, Nick Tumbaras and Chas. G. Y. Higgins, the latter an attorney. All of the men are residents of Provo.

under the co-operative agreement of the state and federal surveys. The report is accompanied by county topographic and geologic maps.

**Eleventh Annual Report for Colorado**, by James Dalrymple, Denver, Colo., state inspector of coal mines. Pp. 94; 6x9 in.; tables.

The American Rolling Mill Co., Middletown, Ohio, has recently published a book of 185 pages entitled **Making Letters Talk Business**. It is a revision of two earlier books on correspondence produced by the company. The price is \$1.25 and the book measures 6x9 in.

Economic and Geologic Papers for the State of Illinois, comprising **Geology and Mineral Resources of the La Harpe and Good Hope Quadrangles**, by T. E. Savage and M. L. Nebel; **Geology and Mineral Resources of the Morris Quadrangle**, by Harold E. Culver; **Geology and Mineral Resources of the Kings Quadrangle**, by J. H. Bretz; **Geology of Northeastern Adams County**, by Louis W. Currier. Illinois State Geological Survey, Urbana, Ill. Bulletin No. 43. Pp. 338; 7x10 in.; illustrated.

## Recent Patents

**Coal Cutter**; 1,485,801. Matthew S. Moore and Herbert Jubb, London, England, assignors to Cowlshaw, Walker & Co., Ltd., London, England. March 4, 1924. Filed May 26, 1922; serial No. 563,970.

**Automatic Feeder**; 1,486,105. James A. Nolan, Bowerston, Ohio. March 4, 1924. Filed April 25, 1923; serial No. 634,618.

**Coal Cutter**; 1,486,529. Nils D. Levin, Columbus, Ohio, assignor to The Jeffrey Manufacturing Co., Columbus, Ohio. March 11, 1924. Filed March 31, 1921; serial No. 457,363. Renewed Aug. 6, 1923.

**Chain-Grate Stoker Link**; 1,486,987. John P. Polster, Toledo, Ohio. March 18, 1924. Filed Sept. 2, 1921; serial No. 497,872.

**Mining-Machine Bit**; 1,487,198. Newton K. Bowman, North Lawrence, Ohio. March 18, 1924. Filed Aug. 17, 1920; serial No. 404,108.

**Mining-Machine Bit**; 1,487,217. James F. Dillon, Crown City, Ohio, assignor to Newton K. Bowman, Bowdill, Ohio. March 18, 1924. Filed Sept. 16, 1920; serial No. 410,593.

**Mine-Car-Loading Device**; 1,487,573. Harry Ingram, Marion, Ill. March 18, 1924. Filed Feb. 9, 1922; serial No. 535,375.

**Tunneling or Mining Machine**; 1,488,066. Alexander Schmidt, Dorog, Hungary, assignor to Maschinenbau-Aktiengesellschaft H. Flottman & Co., Herne, Germany. March 25, 1924. Filed Dec. 30, 1921; serial No. 525,963.

## Obituary

Clarence D. Boyd, manager of the joint traffic office supported by the Southern Appalachian Coal Operators' Association, Harlan Coal Operators' Association, and Hazard Coal Operators' Exchange, at Louisville, died Aug. 29, following a ten-day acute illness of Bright's disease. He had been in poor health for several months. After many years connection with various roads Mr. Boyd resigned as general coal and coke agent of the Louisville & Nashville R.R. May 1, 1919, to establish the joint traffic bureau.

## Coming Meetings

**Association of Iron and Steel Electrical Engineers.** Annual meeting and exposition at Duquesne Garden, Pittsburgh, Pa., Sept. 15-20. Secretary, John F. Kelly, 1007 Empire Bldg., Pittsburgh, Pa.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3. Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

## New Equipment

### Hanger Bearing Has Rollers Tapered to Meet Thrust

A new lineshaft bearing embodying the Timken tapered roller bearing, as well as several new features, recently has been placed on the market by the Dodge Manufacturing Corp., Mishawaka, Ind.

The bearing is a simple unit. There are only five parts to the complete assembly. It consists of two tapered roller bearings mounted on a ground and slotted steel tube and fitted to an accurately machined housing. The ends of the steel tube are threaded to receive clamping collars designed to afford accurate adjustment of the bearings on the tube. This adjustment is

Lineshaft Anti-Friction Bearing

Full utilization of the two bearings for radial and thrust loads is obtained by tapered races housed in this unit.

made at the factory and need not be altered by the user.

The mounting of the tapered roller bearings, as described, assures full utilization of the bearings for both radial and thrust loads. It also adds to the ruggedness of the assembly and is of particular value in resisting the side weave of heavy driving belts.

The method of fastening the steel tube or sleeve to the shaft permits of its use on any commercial shafting. This fastening is accomplished by simply setting up the screws in each of the two clamping collars.

The dustproof feature of this bearing is also of importance. The sleeve on which the bearings are mounted extends from end to end of the housing. Liberal grease compartments are provided inside the housing and outside the tube. The outer ends of the bearings are protected against dust by special metallic grease seals which eliminate friction at this point and positively prevent dust from working in or the lubricant from working out. These grease seals take the place of felt washers or packing.

The tapered roller bearing is constructed on the cone principle which insures a true rolling action. The bearing itself comprises four parts, a cone or inner race with outside taper, tapered rollers, a cage or roll retainer and a cup or outer race.

The cone, rollers and cups are made of electric steel. The rollers and races are heat-treated and each roller is precisely checked for size and accuracy

## Publications Received

**Twenty-Fifth Annual Report of the Mining Industry of Idaho for 1923.** Pp. 221; 6x9 in.; illustrated.

**The Geology and Mineral Resources of Wise County and the Coal Bearing Portion of Scott County, Virginia**, by J. Brian Eby, with chapters by M. E. Campbell and G. W. Stose. A chapter on the **Forests of Wise County, Virginia**, by Fred C. Pederson, also is included. Virginia Geological Survey, in co-operation with the U. S. Geological Survey and the Office of State Forester, Charlottesville, Va. Bulletin No. XXIV. Pp. 617; 6x10 in.; illustrated. This is the seventh of a series of detailed reports on the coal resources of southwest Virginia

by magnetically operated automatic machines. The taper of the roller, which has to carry and adjust the end thrust is constantly checked during production by extremely accurate gages.

The assembly of this new lineshaft bearing is simple. It is only necessary to slip the bearing over the shaft and set up the clamping screw in each of the split clamping collars. It is easily removed by loosening the screws in the collars and slipping the bearing off the shaft.

### Moistureproof Siren

A new electric siren for indoor and outdoor service recently has been developed by the Inter-State Machine Products Co., Inc., Rochester, N. Y.

The fan or rotor is protected by a waterproof housing and a screen placed in the sound projector keeps out all foreign matter. The siren is positively

### Work and Emergency Electric Signal

This device is provided with a waterproof housing and conduit connection to exclude all moisture and dust.

waterproof and weatherproof and can be used outdoors without additional protection. The motor is inclosed in a substantial housing fitted with a conduit connection so that all wiring may be done in the most improved manner, leaving no exposed wires. The horn projector and waterproof housing are made from heavy gauge metal and finished with several coats of red enamel. A specially designed bracket of the swivel type is mounted at the base of the signal so that it can be located in any position and still exclude moisture.

This siren has been improved by the use of a large and more efficient motor, the bearings of which are lubricated by two accessible oil cups.

### Improved Pole-Top Switch

A new disconnecting switch for outdoor service has been developed by the Delta-Star Electric Co., Chicago. This unit is for multi-pole service where two or more elements are to be interlocked and operated either manually or by motor.

The switch consists of two rotating pillars with copper contact blades reinforced by heavy T-iron. One blade is provided with a sleet shield and the other a self-aligning contact. When the switch is closed these two parts are held together by contact springs.

### High-Voltage Line Switch

Both the insulator pillars on this switch rotate when the switch is either opened or closed. By this means the contact blades come together between self-aligning contacts under a sleet shield.

The blades of the switch rotate when being closed. This is accomplished by levers controlled from a special bearing mounted in the center of the switch base. Line wire connections are made to lugs fastened to a small bearing which easily rotates with the blades of the switch. All bearings are fitted for Alemite high-pressure lubrication.

### Hopper-Feed Hand Stoker Has Many Advantages

The McClave-Brooks Co., Scranton, Pa., recently announced a hopper-feed hand stoker suitable for application to hand-fired boilers in the mining field. This stoker has been designed for boiler plants where the owner is disposed to avoid the expense of mechanical stokers but nevertheless needs smokeless, efficient combustion.

The equipment consists of heavily designed hopper-feed fronts and heavily constructed divided kicker-movement grates, as well as extra heavy cut-out bars for the removal of the ash and special clinker shear plates. The specially designed pre-heated air arch is a distinct feature of this stoker.

Extending across the front of the furnace are coal magazines or hoppers of large capacity into which fuel may be introduced by chutes from overhead

### Side Elevation of Hopper-Feed Hand Stoker

The heavily constructed stoker arch is cooled by air driven through the arch. Consequently, this air is also pre-heated before passing through the coking area where it provides an extra supply of oxygen to help complete the combustion of the gases rising from the green coal.

bunkers, a traveling lorry or, if necessary, by hand. The large capacity of these hoppers is a distinct advantage in case the fuel supply should suffer a temporary interruption by clogged chutes or other causes. At the bottom of these magazines are located the coking plates which also extend across the front of the furnace and directly under the main arch.

Coal is deposited on the coking plates from the bottom of the hoppers or magazines and then is fed on to the inclined grates by plungers or pushers that always feed the same quantity at a push, thereby assuring a bed of correct thickness for various capacities. This action, which takes place with each movement or throw of the pushers, underfeeds fresh fuel to the fire.

### Paint for Wall Already Wet

Many people want to paint damp basements, damp concrete and masonry walls, damp building interiors, such as laundries, power-plant walls, etc., where there is an excess of moisture.

Every painter knows one cannot successfully paint a wet or damp surface. If the surface is thoroughly dry and the paint is good and the work is done in a workmanlike manner, a good job of painting, varnishing or enameling will stand much moisture. But it is different when an attempt is made to cover with an oil paint a surface already damp or wet.

The Truscon Laboratories, Detroit, Mich., have brought out a product for coating damp or wet masonry. In fact, it can also be used on wood, although it is preferable for masonry. This material is not an oil paint, as we all know that no oil paint has ever been made which can be applied to a damp surface. This material is known as a hydraulic paint. It contains no oil whatever. It is produced in powder form and mixed with water much after the manner of calcimine or cold water paint.

This material is known as Stuccotex. It is put up in convenient size packages in such colors as white, cream, red, concrete gray, bedford gray, portland gray, tile red.

This material has no relation whatever to an oil paint, nor to a cold-water paint. It differs from either of these. In the first place, it is generally used on cement and masonry surfaces, especially if they are wet, although it can be applied to a dry surface also. In the second place, it is an all inorganic material and non-perishable. It contains no glue, casein or vegetable oils.

## Railroads Might Stimulate

### All-the-Year-Round Buying

**S**PASMODIC interest in the purchasing of coal during the summer is stirred up by various public bodies, and this is indeed well, but the delaying habit is so strong in the public that, if we wish to stir the buyer to continuous action, we need continuous advertising. The railroads are just as much interested as the coal companies, so why do they not advertise by putting a placard conspicuously in their waiting rooms, explaining that the interest of the consumer is to have an unfluctuating market to buy in without shortages and without gluts?

It should be easy to convey to the consumer the story that coal shortages cause prices of coal to rise as they also raise the prices of grain, and it should be easy to show him that both coal and transportation must be excessively costly when both mine and railroad have to be kept competent to do in a few months what could just as well be spread the year through.

Furthermore, it could be urged that a little more foresight on the part of the consumer would keep the miner and railroad employee steadily at work and would maintain a market for the manufacturer and tradesman throughout the year. The railroads, in fact, should advertise the value of steadying markets as helpful to everybody. The idea has not been sold. How could it have been, seeing that it has not been advertised?

## John and Warren Wrangle

**T**HIS monkey-and-parrot time of it that John and Warren are having amuses us. Here is Warren, president of the Brotherhood of Locomotive Engineers, a powerful and normally sane labor union, trying to run a labor-owned coal company down in West Virginia on a business basis—which means he wants to produce coal at wages that will permit the company to break even or maybe declare a dividend. And here is John, president of the United Mine Workers of America, lambasting him for doing it. What Warren ought do with his union-owned Coal River Collieries, if he can't run them without loss at the high wages dictated by John at Jacksonville, is to do it anyway, and hand out to miners the engineers' investment of \$3,000,000 as long as it lasts. That's the way to run a business. Any union mine official will tell you so.

But this labor union, the Brotherhood, has been learning something about competitive business during the last few years. It has been running a bank for one thing. Of course, that may not have been as competitive as some enterprises, partly because a large volume of depositors and investors was guaranteed before the bank even opened its doors. But it was sufficiently competitive so that Warren and his fellow engineer bankers didn't invest much of the money in pure altruism.

When John asked for a big miners' strike loan in 1922, for instance, secured only by John's name in bold black ink, Warren said, No. He wanted to make the loan on a business basis or not at all. He was in the banking business and the bank had to work for what it got. This made John mad. Also it made John pretty mad to think the decently-paid engineers would not quit work and tie up the railroads to help the miners win their strike; but that is only incidental to the present hot time between John and Warren—oh, purely incidental!

And then Warren and the boys who pull the country's throttles bought the Coal River properties. They paid the union scale and tried their best to make the thing go. They probably did everything humanly possible to make it a success on a union-scale basis. But they were in business, and they found that economic forces sometimes cannot be met with thunderous phrases about "no backward step" and the like.

Maybe John can get by that sort of thing, as his income is all collected for him from his own rank and file by the coal operators, no matter whether the rank and file thinks it is a good investment to make or a punk one. But Warren had to get his money in a business. So he told his union miners the jig was up. Either they worked for enough less to make it possible for him to stay in business or down went the mines and nobody worked. So the mines were closed down. Warren at least wouldn't reopen non-union. John ought to give him credit for that.

But John doesn't credit him with anything much, except with "joining other coal operators of West Virginia in an attempt to starve the employees into acceptance of a wage reduction." This is "an intolerable position for a coal company whose stock is largely owned and whose affairs are directed by union men." However intolerable it may be, the locomotive engineers still have the \$3,000,000 they invested in the Coal River Collieries and are probably in position to earn something on that investment if they ever get a chance to run their mine on a business basis. But the fact that they recognize the economic law of supply and demand certainly riles John.

## Summer Coal

**A** GREAT wonder to American tourists who visit Europe during the winter is the extreme coldness and discomfort of the houses heated by inadequate grate fires in front of which one must turn like a spit in order to be toasted on both sides. The reason probably for the meager heating is that the winters are so moderate that the problem of house warming never had to be settled right. Whether that is the real reason one cannot say. Certainly it has never been rightly settled—at least not in Europe.

But while we wonder at Europe freezing in the winter, have we not reason to marvel at the way in

which America swelters in summer? The captain of industry finds his home and his office unbearably hot. He discovers that he must take a long vacation to the mountains, at the shore or in his yacht. If he stays in the city, he gets nine kinds of stiff neck from the fitful breezes of his office fan, which disturbs his papers and delivers to his desk the dust-laden air of the city street.

We have borne with this nuisance so long, however, that it never seems to occur to us that we could have rooms regulated by a thermostat to any degree of heat. We could cool, clean and move the air so that it would give us comfort and allow us to retain all those habiliments that go with dignity—coats, vests, collars and cuffs. Why should not comfort in the summer be as important as in the winter? The Englishman with his draughty house and bucketful of glowing embers is not more sad than your American with wilted collar, perspiring forehead and stiff neck. Some day we shall rise to a superiority over the rises of the thermometer as we have over its downward plunges.

What temperature shall we endeavor to attain? That is a matter for determination. Perhaps ten or fifteen degrees below that of the outside air—a temperature high enough not to chill us on leaving the street but cool enough to keep us active and capable of performing a good day's work, despite the heat. At night we shall sleep and gain strength for the morrow's toil instead of fitfully tossing and watching the passing hours.

The problem of conditioning air is not a new one. In a deep metal mine, the St. John del Rey, the miners are being supplied with artificially cooled air. In many hot American metal mines large volumes of air are being circulated for the purpose of reducing the temperature. The work of the miners is greatly increased by the change, so much so that the companies recognize ventilation as a source of extremely valuable economies. In the textile factories the air is regulated but rather as to its moisture than as to its temperature. If such provisions are made in industry why should they not be provided for comfort?

After a while the electric companies will be buying coal to provide for the demand for summer ventilation and for the operation of air-cooling water sprays. Where ammonia is used, the householder will be using coal to operate his private refrigerator plant and we may find ourselves questioning one another: "Have you bought your summer coal?" Coal men will miss an opportunity if they fail to awaken the public to the advantage of conditioned air.

### Manufactured Fuels Filling Need for Smokeless Coal

ONE POTENT phase of the fuel situation is becoming increasingly important from year to year. This is the production of smokeless fuel. Heretofore the really smokeless coals, so far as the ordinary householder is concerned, have practically all come from the anthracite region of Pennsylvania. The limits of this field have been established with a fair degree of accuracy; both the quantity of coal mined and that yet left in the ground have been computed closely. It may be stated with a reasonable degree of certainty that the anthracite deposits of Pennsylvania will be exhausted within the course of approximately the next

century. Long before that time has arrived the country must have developed a satisfactory substitute fuel.

Though there is doubtless room for improvement in existing anthracite substitutes, nevertheless several such fuels have already reached a fair degree of perfection. The most common of these is probably coke, either byproduct, beehive or gas-house. This fuel being bulkier and more porous than coal must be treated in the ordinary house furnace somewhat differently from anthracite. As it burns with an intense local heat it is liable to warp the firepot of a house furnace unless this is surrounded with water. Its use is most successful in steam and hot-water furnaces.

Of the various other substitutes only two as yet have become important—gas and briquets. Gas possesses the advantage not only of being smokeless, but also of being ever-ready and requiring no kindling for its ignition. It is probably the most convenient fuel known and makes a fire that may be readily controlled throughout its entire range of heat-generating possibilities.

Briquets were at first regarded by the average householder with more or less suspicion. Although those first made in this country were of somewhat doubtful quality, the later product has been much improved. Today it is entirely possible, through a proper heat treatment of the briquet after pressing, to obtain a fuel that is at least as smokeless as anthracite, even though the coal from which it is made is rich in bitumen and consequently decidedly smoky when burned raw in an ordinary furnace.

In making a smokeless domestic fuel from a high-volatile coal it is quite possible to recover certain byproducts which in some degree at least tend to pay for the manufacturing process. While it is a comparatively easy matter to enforce local smoke ordinances against the big industrial plant, it is an entirely different proposition to enforce the same regulations against the small householder, whose name is Legion. It would seem therefore, that our cities will not be devoid of smoke until a smokeless fuel is not only available to the ordinary householder but until it has become economically advantageous for him to burn such fuel in competition with raw coal.

Briquets meeting with the most ready sale today are those either manufactured from fine anthracite or from bituminous coal which has been so heat-treated as to drive off practically its entire content of volatile matter. In treating the highly bituminous coals, with which nature has so richly endowed North America, in such manner as to render them smokeless, in addition to various byproducts, two excellent fuels, both of which readily burn to carbon dioxide and water vapor are produced. Thus while raw soft coal can be burned smokelessly only with difficulty gas and coke or heat-treated briquets may be burned to invisible vapor without appreciable hindrance.

This country's supply of bituminous coal is almost limitless; its store of naturally smokeless coal must soon be exhausted. Already several processes are available whereby excellent smokeless fuels may be made from inferior natural products. The use of these fuels must naturally increase from year to year. Fortunately, smokeless manufactured fuels—coke and briquets—are superior to the natural product in heat content. Furthermore as a rule they contain less ash.

Mud Sprayer in Action

## Is Mud Equal to Rock Dust For Mine Protection?

Utah Superintendent with Plenty of Air-Slacked Shale at Hand Saves Grinding Costs by Mixing Dirt with Water and Spraying It Through Rooms and Entries from Home-Made Pumping Machine

Mud-Sprayed Heading

**W**HY not "mudize" a coal mine instead of rock dusting it? If the same degree of safety from coal-dust explosions can thus be attained at one-fourth the cost and with greater ease, then why not do it? Many a coal-mining man in the Rocky Mountain regions has been asking himself these questions since the idea of "mudizing" was conceived by W. J. Reid, superintendent of the Lion Coal Co.'s mine at Wattis, Utah. If air-slacked shale, adobe or other easily friable clays can be mixed with water and effectively sprayed on coal-mine roofs, ribs and roadways, is there any good reason why a mining company with such material available should go to the trouble and expense of pulverizing hard rocks or shales for the purpose?

As yet nobody knows positively that the new mud process is as efficacious as the better known fine, dry rock dust. Even Mr. Reid, who is better informed than anybody else, being the only man who has done the thing extensively, cannot be positive; his mudized territories have never met the test of a spreading mine explosion. Although pretty well convinced and unable to see any good reason why the scheme should fail, he is trying his best to prove or disprove the theory. Right now he is running a series of tests in a 50-ft. length of corrugated iron pipe such as is used for storm culverts under highways. He is mudizing sections of the interior of this pipe to see whether coal-dust explosions will jump the protected areas. Also he is figuring up every other kind of trial he can think of, short of a mine explosion, to determine just what effect the mud will have under all circumstances.

His mudizing idea is attracting widespread attention, as is his patented mud-spraying machine for mine use, which is still in the development stage. The mine inspectors of Utah have not yet put their stamp of approval on mudizing, but they are watching it closely. Since rock dusting is required in Utah under the new state mine safety code, it is difficult to say whether mudizing can be interpreted to mean rock dusting; but nobody is putting anything in the way of proving out

the idea and eventually it may be accepted as standard rock-dusting practice.

Mr. Reid says the mudizing idea dawned upon him while he was watching a machine shoot cement onto outside wooden construction to render it fireproof. If cement at so much a hundred pounds was a protection against fire, why wouldn't ordinary air-slacked Utah shale, mixed with water, do just as good a job at next to nothing a hundred? The hills all around the Wattis mine are full of the right sort of dirt. In fact, at one point close to the tippie, at the bottom of the long tramway that brings the coal 1,000 ft. down the mountainside from the mine, a bank of this dirt located in a small cut constantly sloughs off and slides down over the track. It has to be shoveled away and is a constant harrassment. Why not see if it could be put to use?

A little of this dirt was shoveled through a screen to remove broken rock and the coarsest of the material. Then it was mixed with water and put through the gunning machine. It stuck to the woodwork splendidly. But did it really fireproof the wood? To find this out, Mr. Reid picked up some broken pieces that were thoroughly covered and carried them home. Into the cookstove they went while a hot fire was burning. He let them lie there for several minutes and then lifted the lids, wondering whether he would see wood ashes to mark a failure of his idea.

### MUDIZED WOOD NEARLY EXTINGUISHES COAL FIRE

The sticks of mudized wood not only lay there unburned; they had almost put out the coal fire itself. So in this way, at least, the method was effective.

The next day a scheme for mudizing the whole wooden weighhouse and tippie went into effect. A shortage of water in the region at the time made it advisable to render the tippie as fireproof as possible and it was done with just plain mud from the mountainside. To-day that wooden tippie is plastered with it, and the Lion Coal Co. expects no loss by fire.

Thence the idea spread to the mine. If mud worked well in the tippie it ought to be good protection against

### MUD VERSUS ROCK DUST

Not any too much is known yet about "mudizing" mines; but from present knowledge it seems that such mining companies as have available a supply of the right kind of dry, loose clay or air-slacked shale certainly can shovel it through a screen into a tank full of water and spray the resultant mud through rooms and entries much cheaper than they could rock dust the same areas. The mud has other advantages that rock dust hasn't, as explained in this article. But there is one big main question yet to be answered: Will this mud stop an explosion that has been initiated elsewhere? It is evident that the mud, when it has thoroughly dried on roof ribs and floor, presents a slightly dusty surface. But it remains to be proved whether this is dusty enough. In any event, many mining men are watching Superintendent W. J. Reid's work with interest.

the inflammability of coal dust. So Superintendent Reid went to work on the problem of mudizing the mine.

He devised a crude machine mounted on a mine-car truck, in which dirt and water could be mixed and pumped by a centrifugal pump through a peculiar flat nozzle that produced a well-divided spray. With this device mud was plastered through considerable lengths of entry. Many changes have been made in the machine from time to time and much experimenting has been done to learn just what the paces of the device are. Thus

Close-up of the Mud Slinging Tank

The machine, which is self-propelling, bears a tank 10 ft. long and 4 ft. wide capable of holding a ton of shale dirt in a one-to-two mixture of water. A 20-hp. motor, drawing power from the trolley line, drives the truck and runs both the stirring paddle wheel which keeps the mud in suspension and the centrifugal pump which sprays the liquid through the nozzle. The mud is delivered onto a fan-shaped plate and is deflected by blades set on the face of the plate. It costs but 50c. a ton to load this machine for service and with it one operative can cover from 2,500 ft. to 4,000 ft. of entry 20-ft. wide in a day.

far the Lion Coal Co. is eminently satisfied with its performances, and the Wattis mine will soon be mudized from portal to rooms.

The mud is first shoveled from the thoroughly slacked face of a shale bank near the tippie. It goes through a twenty-mesh sand screen directly into a pit car and is then ready to be hauled up the tramway to the mine. The cost of this "preparation" probably is not over 50c. per ton. This is far less than the total cost of producing and grinding ordinary mine shale.

About a ton of the material is loaded from the pit car into the tank of the mudizing machine with water in the proportion of about three to one by volume. The mixture is kept constantly stirred by the machine and is discharged by the pump through the nozzle as the machine runs slowly through the mine under its own power.

The average application varies in thickness from  $\frac{1}{4}$  to  $\frac{1}{2}$  in. The liquid seems to penetrate perfectly into cracks and crevices and to effect complete coverage of all exposed surfaces on roof and ribs. Though the angle of deflection from the fan-shaped nozzle is such that the mud does not strike directly upon any mine surface lower than a line 30 in. or so from the floor, the ribs below that line are well splattered and the roadway is heavily encrusted.

#### MUD SPRAY WASHES DUST DOWN

The first effect of the spray is to wash down all the coal dust that may have accumulated on roof and ribs, leaving the layer of pure shale. The value of this is apparent when it is remembered that by this process practically all inflammable accumulations in the entry are carried to the floor. And on the floor it is deposited as a thorough—and presumably non-explosive—mixture

of coal and shale instead of in super-imposed layers of coal dust and rock dust.

Of course this caked layer of mixed material on the roadway is partly broken up by travel, especially close to and between the rails, and it might be said that in this manner the coal dust might be brought to the top in a dangerous film.

A careful examination of this floor material, after it had dried thoroughly, indicated, however that in the pulverizing process the shale breaks down to the same talcum-powder fineness as the finest coal dust and that therefore the shale on the roadways should always be ready to fly into suspension with the coal dust under the force of any rush of air such as that which precedes an explosion.

Over part of a roadway surface, where the floor is little disturbed, however, the mud and the coal dust remain caked together in what is probably non-flammable form. A virtue of this caking is that mine sanitation is much improved. Such manure, offal or other organic matter as might be deposited throughout the mine is effectively sealed over.

The plaster of mud on roof, timbers and ribs in the Wattis mine has the light color characteristic of average mine shale—even a little lighter, perhaps—and therefore possesses all the advantages of illumination which are lent by shale dusting.

The appearance of creep in the roof or ribs is easily detected. New cracks probably will show up more plainly than they would in entries that had been dusted with dry pulverized rock because of the sharper delineation of the edges of the crack. Thus the men in the Wattis mine feel that they can more readily detect a developing case of bad roof.

Mr. Reid also thinks that bottom heaves in clay are delayed or prevented by the liquid spray. The stuff is applied in such thin liquid form that deep cracks are filled and a mine bottom is so thoroughly sealed from the air that some causes of heaving are eliminated.

#### MUDIZING REDUCES DUST ACCUMULATIONS

Naturally the main interest in mudizing centers in the question: Will this mud stop the spread of an explosion? In order for it to do so it probably must present a dusty surface bearing enough finely divided shale dust, ready to be blown into suspension, so that the work of loose rock dust may be accomplished. The only answer to the question is this: The mud dries in about 36 hours, or 48 hours at the most. When it is dry, the coating on roof and ribs offers a chalky surface from which dust can be rubbed in a thin film with the finger tips, but nobody knows definitely whether there is enough of this fine shale dust to stop an explosion.

It is worth noting that the mud, when it is first applied, fills even the finest cracks and the most minute niches. While the larger depressions and ledges in roof and ribs are not poured full, they at least fill out flatter and flatter with each succeeding application so that the tendency of the mudizing process is to reduce the opportunity for fine coal dust to accumulate.

"But only a trifling accumulation is necessary in order to make a mine dangerous," say the numerous critics of mudizing, when they first hear of it. "No mine can be prevented from spreading dust about on the air and through spillage from cars. And what if this accumulation is piled up between trips of the spraying machine? Is your mine safe, then?"

"Well," reply such defenders of the scheme as P. H. Burnell, operating head of the Lion Coal Co., "The thing to do is keep your working places mudized right up close, use lots of water at the actual face and make your cars tight. Then you will have reduced the danger of dust accumulations to the lowest point. Nothing is perfect, but it seems to us that if you do those things you get pretty close to perfect mine protection against dust."

One other point is worth discussing with regard to the possible action of mud with a passing burst of flame. The caked layer of dirt, once thoroughly dried in the mine, is compact enough to adhere closely to roof and rib surfaces, but it will pulverize easily between the fingers—so easily, in fact, that it seems probable that the heat and force of an explosion traveling through an entry might easily reduce a part of the layer to finest dust which would be blown into suspension and thus participate in subduing a coal-dust fire in the recoil if not in the initial blast.

#### ECONOMY OF SCHEME IS OUTSTANDING FEATURE

A most attractive feature of mudizing as it is now practiced at Wattis is its economy. The dry dirt—a sort of air-slacked shale—costs but 50c. a ton at the mine portal, ready for the tank of the spraying machine. Power is a small item, for a 20-hp. motor operates the entire unit, supplying power for travel, for agitation in the tank and for spraying. One man operates the outfit. The machine should travel about 100 ft. per minute when it is spraying and the experience of the Lion Coal Co. is that it can easily cover 2,500 ft. of entry a day, allowing for all sorts of delays short of actual breakdown. An average day's work might cover 4,000 ft. of entry.

Mr. Reid cannot help comparing this performance with that of men sprinkling with water. In the Wattis mine a man equipped with a length of hose, whose job it was to proceed from hydrant to hydrant, washing down the mine, almost never covered more than 1,000 ft. in one entire day. Furthermore, it often was possible for him to assert that he had sprinkled sections he had never entered. But with the mudizing machine the evidence is so plain that no operative ever can allege more than he actually has done. In other words he must do his full stint or show good reason why. And the capacity of the machine is three times that of the ordinary sprinkler at one-third the labor cost. A tankful of the mixture will cover 800 ft. to 1,000 ft. of 20-ft. entry. Of course this distance will vary with the size and condition of the roadway and should be greater than 1,000 ft. on repeat coatings.

At intervals through the mine it is necessary to have a supply of the dirt ready for the machine. As the material makes good stemming, piles of it are dumped in rooms. This leaves it handy for the machine when it is working in room entries and keeping up with the advancing faces. But the main supply is hauled into the mine in pit cars and spotted along the route that the machine is scheduled to follow in each tour. The process of recharging the machine is simply one of shoveling dirt into the tank from a pit car on a parting and of filling up the tank with water from the lines, which are necessary in all mines of Utah under the state code.

The self-propelling machine which Superintendent Reid devised, but which is being replaced by an im-

proved type, consists of a tank 10 ft. long, 4 ft. wide and 16 in. deep made of sheet steel and angle iron. The entire top comprises three lids easily removed. The bottom of the tank pitches slightly from both ends to the middle, where an agitator paddle wheel bearing eight spokes revolves constantly above a 2-in. outlet pipe which feeds the mixture by gravity down to a centrifugal pump under the tank. The pump discharges the liquid through a pipe of 1½-in. diameter to an outlet on the apex of a fan-shaped steel pan nozzle. This

Canyon Down Which Lion Tramway Passes

The tramway can be discerned on the left side of the valley. At places along the roadway is found the fine weathered shale that is turned into mud by the rains and is used by Mr. Reid to mudcoat his entries and return airways. Mr. Reid cleans his tramroad of fine detritus and turns it to good use by covering his headings with it.

fan-shaped plate, elevated at an angle of about 45 deg. from horizontal, bears on its face an arrangement of blades standing on edge, so curved and placed as to deflect the mud spray correctly. The spray is further aided by an upturn around the rim of the plate.

The motor, mounted under one end of the tank and operated from the line through a trolley pole, drives the truck, agitator and pump. It operates at 860 r.p.m. and transmits power to a main vertical shaft through a four-to-one bevel reduction gear. Further speed reduction in the transmission of power for locomotion is accomplished by a steel worm on the lower end of the main shaft engaging a bronze wormwheel on the drive shaft. A sprocket and chain connect the drive shaft with one of the truck axles, affording the desired travel of 100 ft. per minute. Another set of sprockets and a chain on the opposite side of the truck make the drive four-wheel.

#### AGITATOR RUNS CONTINUALLY

The agitator in the tank is driven at 107 r.p.m. through a gear reduction from the main shaft. It revolves all the time the motor runs, though the truck may be stopped or the pump halted at any time by a shifting of gears. This constant agitation keeps the mud in the tank from settling and choking the pipes and thereby eliminates any likelihood that the pump, becoming clogged, will break. The pump is driven at 1,720 r.p.m. through a speed-increasing gear and shaft equipped with a flexible coupling to absorb shock.

The new type of Reid machine will have two agitators, one whirling on either side of the main feed pipe leading to the pump. The single paddle wheel did fairly well but in the 10-ft. tank too much mud was precipitated at the far ends.

In the experimental work with the Reid machine all sorts of places in the mine were mudized. It was recognized that a machine on a track cannot reach every opening in a mine that needs rock dusting and some

Detail Drawing of Mud Sprayer

The agitators prevent the precipitation of the mud, being kept at work even when the pump is not operating. As the dust with which the water is mixed is extremely fine it is kept in suspension with a minimum of agitation. By using two agitators the dirt even at the car ends shows little disposition to settle.

## North Carolina Mines May Have Byproduct Ovens

BY J. H. ROSE

Erskine Ramsay Coal Co., Cumnock, N. C.

THE two mines in operation in the Deep River coal field of North Carolina are located approximately six miles northwest of Sanford, the coal field lying in Lee and Chatham counties. Deep River flows through the field in a generally northeast direction. It is traversed in a northwesterly direction by the Atlantic & Yadkin R.R. between Raleigh and Charlotte, and it is within convenient reach of the Seaboard Airline Ry. that passes through Sanford. A branch of the Atlantic Coast Line comes into Sanford and connects with the Atlantic & Yadkin at that point.

The strategic location of this coal field in relation to a large surrounding steam-coal market is unusually favorable. It lies 180 miles east of the great Appalachian coal regions. The coal occurs in the Triassic or New Red Sandstone formation, in the shape of a long synclinal trough, having a northeasterly direction. Tracing the coal seam from the outcrop to the diamond-drill holes shows the measures to be pitching on an average of 8 deg. At the bottom of the Farmville slope the measures are pitching 3 deg. The main slopes driven off from the Cumnock shaft are now showing the measure to be pitching 10 deg. The two mines (about a mile apart) and exposed surface measures overlying the coal indicate a large acreage of comparatively flat measures.

### FIELD MAY COVER 25 SQUARE MILES

The rocks consist of sandstone, shales and fireclay, with some interbedded coal seams extending over a limited section. A section of the coalbearing measures, as shown by the mine operations at Cumnock and Farmville is set forth in Table I.

Records of diamond drillings and mine operations have proven approximately 4,250 acres of workable coal, definitely in the field. A strange geological freak will be developed should the exploration proposed fail to prove up from 10,000 to 12,000 acres of workable coal in addition to the 4,250 acres just mentioned.

The coal-bearing strata contain a number of coal seams of varying thickness and quality. Only one of

attention had to be given to the trackless entries and aircourses which every mine has to watch. Dry rock dust can be blown into intake air with good results but mud can hardly be distributed in that manner.

To meet this difficulty Mr. Reid and his men used hose between the machine and spraying nozzle. At first they tried only a 50 ft. length. The results were so good that they added more and more hose until finally they were using 300 ft. and were able to spray 50 ft. beyond the end of the line. They believe they can use as much as 500 ft. of hose and still get sufficient pressure from the pump to spray mud successfully, although it may be necessary to thin down the mixture.

Thus they are perfecting the mudizing idea at Wat-tis. They may not have it worked down to a fine point, but they feel that they are approaching this stage. It is possible that they have gone far enough already to reduce greatly the cost of dust protection in those mines which have available a supply of dust material of the proper quality for this work.

these seams is commercially workable—it being known as the "Four foot" seam. It occurs at the top of the coal-bearing strata. However, tests are now being con-

Table I—Coal-Bearing Measures, Deep River Field, North Carolina

Sandstone cap rock	10 to 14 in.
Draw slate	2 to 6 in.
Coal ("Four ft." seam)	37 to 54 in.
Blackband ore	15 to 18 in.
Low-grade coal	20 to 30 in.
Fireclay, slates, shales	25 to 35 ft.
Blackband	2 to 3 ft.
Coal	24 to 32 in.
Blackband	18 to 34 in.

ducted as to the possibility of utilizing the low-grade coal for mechanically fired boilers for steam standby power plants operated by the larger power companies located in the state. A recent analysis, made by the state geologist, of the coal is given in Table II.

Dependable records of coal cuttings made and diamond drillings, indicate an average thickness of the "Four foot" seam, of 42 in. exclusive of 2½ in. of bone coal underlying the seam.

The large power companies in the state are exhibiting much interest in the possibility of locating a byproduct plant at one of the mines and have engineers in the field

Table II—Analysis in Four-Foot Seam, Deep River Field

Moisture	1.15
Volatile Matter	24.89
Ash	5.64
Sulphur	3.17
Fixed Carbon	57.03
B.T.U.	14,230

working in conjunction with the coal companies. The coal yields large quantities of illuminating gas, ammonia and coal tar.

Both mines are being rapidly developed and by the end of this year a production of 600 tons per day is anticipated for the field, the combined production of the mines at this time being 300 tons per day. The market for this coal far exceeds the production and a good price is realized for the coal during the entire year. Neither mine lost a day's time during the past eighteen months on account of no market for coal.

# Germany's Return to Honest Money and Economy Marked by Speedy Recovery

BY E. J. MEHREN

Vice-President, McGraw-Hill Co., Inc.

**N**O COUNTRY in the world today is, from the economic viewpoint, so interesting as Germany. She occupies the spotlight in Europe. What is to be her future?—is the question that everyone in the old world is asking.

The answer to that question no one can tell. The problem is complicated. But this even the casual visitor to Germany can say: *Germany has made tremendous strides since the war; she is showing extraordinary recuperative power—against tremendous handicaps; she has worked a financial miracle since November of last year; and, finally, no nation that shows Germany's potential strength can be permanently kept down, can be crushed.*

These observations, let me repeat, even the casual visitor must make. The signs are written everywhere: in a people again well nourished, in a public administrative ability (irrespective of party) that was able without new revolution to stabilize the currency, in a returning hope that Germany can again rise. There is not buoyancy of spirit, but there is a deep-founded confidence that the nation is not going to pieces.

The situation is in sharp contrast to what one expects. In America we hear of the wrecking of the currency, of the sufferings of last winter, of the difficulties under which her industries labor in securing raw materials and finding markets. Upon these reports—which of course, are correct—we paint with our imaginations a country on the verge of despair, a disrupted industry, a tottering government. The surprise is a great one—and, if one is fair-minded, he must come away with deep admiration for what has been accomplished.

Let us briefly paint the picture of Germany's economic circumstances:

Under the Versailles treaty or as a result of it she lost heavily of her iron and coal deposits—in Alsace-Lorraine, the Saar and Upper Silesia; she lost her colonies, her foreign investments, her shipping, her export organization and its connections; she has a large part of her territory under the control of her former enemies. In addition she has been through an exhausting war and political revolution.

These conditions are not new; they existed when I was in Germany just four years ago, in the summer of 1920. The result was what might have been expected—an under-fed, discontented people, a disorganized industry, and an all-pervading discouragement, unrelieved by any ray of hope.

Since then, since 1920, two other financial disasters have forced themselves into the picture—the occupation of the great industrial district of the Ruhr, and the wrecking of the currency.

With these added calamities one should logically expect that conditions

would be worse instead of better, that the despair would be even blacker than before.

And yet conditions are as I have described—immeasurably better. Here is a nation on the up-grade, rather than the down. Here is a nation to be reckoned with economically, not to be ignored; here is a nation that is sure to be an important factor in the world's industry.

This last is a bold statement. I realize what terrific handicaps the rest of the world can put upon Germany if it wishes. It can keep Germany impotent, but it is my belief that it will not do so. Sentiment, moreover, will play no part; commercial considerations alone will lead to trading with Germany. Other nations will want to sell to the markets of a reviving Germany. If they sell to Germany, they will buy from Germany, and if they buy from Germany, a prominent place in world affairs is assured her by the potential strength she is now so conspicuously displaying.

Let it be clearly understood that the path of recovery for Germany is not an easy or a quick one. She is not out of difficulty. The economic handicaps recited above are still upon her; some of them are being slowly removed—such as the absence of shipping and foreign commercial connections; some of them—such as the lack of colonies—may never be removed. But a nation that under present handicaps has recovered as she has done will rise despite the obstacles that a commercially minded world is likely permanently to place upon her.

## THE TURNING POINT

The great German economic miracle was wrought in the closing months of 1923 and the early part of 1924. Early last autumn Germany truly, to use the words of Basil Miles, administrative commissioner for the United States in the International Chamber of Commerce, was at the cross-roads. Directly ahead—on the road she was traveling, the road of unbalanced budgets, of state subsidy of the railroads, of currency debasement—was revolution, industrial suicide, destruction. To the right was a stormy path, extremely difficult, beset possibly by disorder, possibly by revolution, but leading, if the difficulties could be mastered, to economic soundness. It was the road of a stabilized currency, with its accompaniments of balanced budgets and governmental economy. Germany chose to go to the right, to take the difficult road, to bear the stress of financial reform and currency stabilization. She did it at a time, too, when the situation in the Ruhr was at its most critical stage, when strong forces were seeking to pry loose the Rhineland and erect it into an independent state, when the attitude of Bavaria toward the rest of Germany was much in doubt. But she

went on, nevertheless. The government declared that the mark should be stabilized at four trillion 200 billion to the dollar. There was a severe contest with the mark speculators, but by severe measures the government won. and since November, 1923, legally, and about Jan. 1, actually, the rentenmark has stood at 23.8c. to the dollar. There was no revolution.

Germany is beyond the cross-roads and has chosen rightly. The future is long and difficult, but there is health where there was disease, there is hope where there was despair.

The severest present industrial handicap is lack of credit. The great credit reservoirs were nearly or entirely wiped out by the fall of the mark. Further, there was no incentive to save; industries and individuals converted the tobogganing mark into goods as quickly as possible. Today the credit resources of the banks are estimated at one-tenth the pre-war amount. When credits are obtained the interest rate is 2½ per cent per month for the very best security.

Wages are at approximately pre-war level. Prices, as of July 15 (according to the *Frankfurter Zeitung* index, the highest index I could find and which takes in ninety-eight commodities) are 34 per cent above 1913. (The government's index for wholesale prices is 12 per cent above 1913.)

Efficiency of labor has increased notably and is still increasing. I heard no general complaint against the working man in Germany as I did in England.

Unemployment, while fairly large just now, is not as great as that of Great Britain, and does not present the all-engrossing problem in Germany that it does in the British Isles.

The works councils, elected by the workers, are said by the employers to be a good influence. They help smooth out difficulties and, in general, have not been radical.

Hours of work per day are increasing.

The coal supply, which by its shortage was expected to be for many years a serious handicap to German industry, is now more than ample, on account of the very large development of lignite deposits.

The heavy taxes imposed on industry and individuals are beginning, under the stabilized rentenmark, to yield a good revenue. Recent figures show a surplus that has been used to retire obligations.

There is much more to be said and the details just given need elaboration. But these few particulars will help to fill out the picture as I saw it—the picture of an industrial nation again on a sound basis, well organized, confident that somehow it will work out its difficulties and play a part in the world of industry and commerce.

Berlin, Aug. 13, 1924.

## Nation Is Using Less Coal as It Finds Price Too High

With Same Coal Railroads Give Eighty per Cent More Service—Utilities Make Coal Go Twice as Far as in 1915

By F. C. HONNOLD

Secretary, Illinois Coal Operators' Association  
Chicago, Ill.

**W**HENEVER clothing or any other personal or household gear advances greatly in price, we are all more careful both of the purchase of such items and in their subsequent use, making every effort to prolong their life and serviceability. The same is true with respect to food. When times are flush and we have plenty of money, it is our natural inclination to buy other things than necessities and to indulge ourselves in luxuries to a possible point of outright extravagance. When times are hard all such items are eliminated and we begin to consider the need of not only confining ourselves to actual necessities but utilizing, wherever possible, the lower priced offerings.

Just such a situation has arisen with every coal-consuming industry in the country as a result of the steadily advancing price of coal during and since the war. In 1915 the railroads of the country used, in round numbers, 106,000,000 tons of bituminous coal and during that year hauled approximately 275,000,000 ton-miles of freight. With the much greater volume of business done in those years, the quantity of coal used by the railroads in 1917, 1918 and 1920 varied from 133,000,000 to 135,000,000 tons each year and with an average cost approximately twice that paid for engine fuel in 1913.

As a result, every device both in the way of change of equipment and more economical use of fuel by employees was introduced. The net result of these efforts is to be found in the published figures of the Interstate Commerce Commission for the calendar year 1923. In this year the railroads carried the heaviest tonnage they had ever handled in any previous year of their history, amounting to the astonishing total of revenue and non-revenue freight of 457,000,000,000 ton-miles—almost twice the service rendered in the year 1914. Despite this showing, their use of coal amounted to only 109,000,000 tons, barely 3,000,000 tons over their use in the year ending June 30, 1915—an increase of only slightly over 2 per cent in coal used as against 80 per cent increase in tonnage hauled. Nor was this accomplished through substitution of other fuel. The use of oil at the present time constitutes only about 8 per cent of the total fuel requirements of the railroads and has shown an increase of only about 2 per cent in the past three or four years.

As another illustration of the effect of increased cost of coal, we note the rapid growth of the so-called super-power plants—public utilities providing electric energy for sale through a large territory and for a wide variety of uses.

Going back to the period slightly before the war, say 1915 and 1916, a kilowatt-hour of power was generated from the consumption of about 5 to 6 lb. of coal, some specially inefficient plants using as much as 10 lb. By 1919 a kilowatt-hour was being generated by 3.2 lb. of

coal, and in 1923 the coal used per kilowatt-hour had been reduced to 2.4 lb. At some of the most recently completed power plants a kilowatt-hour of power is being made at the astonishingly low consumption of only 1 lb. of coal.

This cheap provision of power for several years past has been and at the present time is to a rapidly growing degree displacing the individual power plant at which the use of coal was very much heavier. As a result of this change the increased use of coal at public-utility power plants throughout the United States for the five-year period from 1919 to 1923 has amounted to less than 3,000,000 tons, whereas the output of these plants has increased 50 per cent.

In addition to the foregoing also, we have at the present time to reckon with fuel oil, which is making itself felt in a competitive way at a great many points.

Odd also as it may seem to some, the great improvement in the transportation service of the country as a whole has greatly affected southern Illinois mines. With more cars and more engine power Eastern coal-carrying lines are in position to care regularly and fully for the growing markets of their coal-mine operators in this Western territory.

In times past a notable lack of equipment and other facilities to some extent isolated these Western markets from Eastern producing mines, especially during the late fall and winter months, and during that portion of the year southern Illinois mines have always enjoyed their best running time. Already a large part of this advantage has been swept away.

## Coal Company Raises Milk as a Sort Of Side Line to Mining Coal

**I**N THE group of pictures on the opposite page are illustrated a few steps of the United States Fuel Co.'s venture into dairying on a remodeled ranch near Hiawatha, Utah. The company originally bought a ranch of the varietal wild-west movie type, Fig. 1, with corral fences built of stakes and with sod-thatched log huts strung around the place. A dry arroyo ran along the back edge of the corral. The place was wont to raise a few cattle and some of the goats which range through the piñon of the foothills.

Now it is all changed. The dry arroyo still lies where water and the Almighty put it, but the rest of the ranch is different. A comfortable ranch house, Fig. 2, has been erected in the midst of a collection of good wooden sheds to house machinery and chickens, and a power and light line has been built to the ranch to supply illumination in houses and barns and to run the electrical machinery including milking devices. The ranch is irrigated with water brought down from the company's watershed back in the mountains.

A set of modern farm barns, Fig. 3, has been erected, a herd of milk cows has been purchased and the company has gone into the dairy business, distributing milk through its mining town of Hiawatha, Utah, and other communities within reach. One object of the enterprise was to guarantee the company's employees an adequate supply of milk hauled in so sanitary a way that the health of the communities would be safeguarded. The model dairy barn, Fig. 4, shown on the opposing page, is equipped with steel stanchions and feed carriers, and is otherwise built to house contented cows.

NOTE—From address delivered at meeting held by Lions Club at Herrin, Ill., Aug. 20, to ascertain causes and cure of present inactivity of southern Illinois mines.

# Bad Water Made Suitable for Domestic and Power Plant Use by Treatment and Purification

Water Usually Requires Less Treatment for Domestic Use Than for Steam Power-Plant Supply—Accumulation of Scale in Boilers Often the Greatest Operating Difficulty—Any Water Can Be Made Suitable

BY FRED L. SERVISS

Brookland, Washington, D. C.

**I**NJURIOUS substances occur in practically all water. However, when the water is to be used for domestic purposes the impurities generally are less objectionable than when it is to serve as boiler feed. The least desirable features in domestic water are turbidity, color, taste, odor, pathogenic bacteria and hardness. Though ordinary hardness is to be avoided in boiler-feed water, it is not hygienically objectionable. The impurities present in water usually are detrimental to boilers or interfere with their proper operation. The troubles from impure feed water are formation of scale, corrosion, foaming and priming.

Objectionable matter usually can be removed without difficulty from water for domestic use, but to render some waters suitable for boiler feed may require elaborate treatment. In the treatment of domestic water some of the color may be eliminated by filtration and all of it by chemical means. Water from swampy watersheds is characteristically colored, the colorization being produced by the growth of certain algæ on the water surface. Where water is drawn from lakes or reservoirs it may in the spring or autumn become obnoxious owing to its odor and turbidity, for at these seasons the water may be overturned either by being warmed by the sun's rays or by contact with the air. However, as water is a poor conductor of heat as well as a poor radiator, the changes in temperature will not be as great as those reached under similar conditions by solid rock masses.

## TEMPERATURE VARIATIONS IN RESERVOIRS

The temperature of lakes and reservoirs is of great importance where it is desirable to obtain water of good quality and uniform temperature. Seasonal changes of temperature, especially in deep ponds (50 ft. and deeper), may produce vertical currents and thus the water will vary in quality at different depths.

If a series of temperature observations are made throughout the year in any lake or reservoir, and at different depths, it will be noticed that the shallower depths show the greatest temperature ranges and the lower depths (usually below 50 ft.) show little or no variation in temperature. In summer the deeper layers of fresh-water lakes are quite cool because water is at its greatest density at 39.2 deg. F. and the water which becomes cooled to this temperature in the winter naturally sinks to the bottom and when there the low conductivity of water prevents the warmth of the sun being communicated to it.

In the cooler seasons of the year the bottom temperature is at 39 deg. F., and it may be even below that if during severe weather the water has been stirred by high winds. The several water layers will lie in the order of their density, the temperature increasing up-

ward to within a few feet of the surface, where it will approach the atmospheric temperature or freezing if the surface is covered with ice. The water will remain in this state until the weather warms the surface to the temperature of the bottom layer, causing a state of unequal equilibrium, and because of this unstable condition circulation will take place from the top to the bottom.

This phenomenon is known as the working or overturning of the water and takes place in early spring and autumn. During the quiescent period of summer stagnation may occur, and if much organic matter such as dead leaves and plants, is present, may continue until all the available oxygen of the water is consumed. The water then becomes darker, has a disagreeable odor and taste. With the overturning of the water, especially in the autumn, this decayed matter is stirred up and so brought to the surface.

If a pond or lake is less than 25 ft. deep the temperature variation is not great, for such relatively shallow ponds are easily stirred to their depths by the wind, thus keeping the temperature equalized. These shallow sources usually produce turbid water which needs filtering.

Tastes and odors although often harmless are nevertheless objectionable in a domestic-water supply; they usually are due to the same cause as color. They may be removed by aeration and filtration or by chemical means. By proper location of off-take pipes pure water may be obtained throughout the year. In deep artificial reservoirs an auxiliary low off-take pipe usually is provided for drawing off the impure and stagnant water in the autumn.

## HARDNESS EITHER "TEMPORARY" OR "PERMANENT"

Hardness may be defined as that quality the variation of which makes it more difficult to obtain a lather of suds from soap in one water than in another, and is direct evidence of the presence of scale-forming impurities in the water. It is objectionable in domestic water used for washing or the laundry because much soap is consumed in eliminating the impurities before a lather can be obtained.

Hardness is classed as "temporary" or "permanent," the distinction being that temporarily hard water may be softened by boiling, whereas permanently hard water must be treated chemically to render it soft. Temporarily hard waters are those containing bicarbonates of calcium, magnesium or iron, which are removed by boiling, the bicarbonates being reduced to normal carbonates which are practically insoluble and are precipitated from the water. The familiar "fur" in a tea kettle or the boiler crust in a boiler are the precipitated normal carbonates.

Water containing no other impurities than the carbonates or bicarbonates mentioned may be softened by boiling. Permanently hard waters are those containing the sulphates of calcium and magnesium, principally calcium sulphate, which can be precipitated only by heating to near 300 deg. F. or removed by chemical treatment. The total hardness of a water is the combined temporary and permanent hardness, which may be determined in many ways, the most accurate being to compute the total hardness from the chemical analysis of the water. The soap method may be used to obtain an approximate result, but it is not to be recommended.<sup>1</sup>

The hardness of water is estimated in "degrees." In France and in some chemical laboratories one part of calcium carbonate (or its equivalent of other impurities) per 100,000 parts constitutes one degree. In the United

accumulates to any extent, the life of the boiler may be shortened, and its condition eventually may cause an explosion. The removal of impurities which cause a water to be permanently hard requires an elaborate chemical process and will be discussed under the treatment of water for boiler use.

Contamination of domestic-water supply by sewage is not necessarily objectionable, but there always is the possibility that domestic sewage is contaminated with pathogenic bacteria, especially germs of cholera and typhoid fever. *Bacillus coli* (*B. coli*) are bacteria present in great quantity in the intestines of human beings and some animals, and are more tenacious of life than either the germs of cholera or typhoid, so that in the sanitary examination of a water the absence of the *B. coli* group is taken to be certain indication of the

### An Indianapolis Purifying Plant

Water system of water softening, a combination chemical and heat treatment, as installed at the Indianapolis plant of the Merchants Heat & Light Co. by the Power Plant Specialty Co. of Chicago. The large tank is the heater and precipitator, the smaller tanks are filters and containers for lime and soda ash. The plant has a rated capacity of 6,000 hp.

States one degree is one grain per U. S. standard gallon or one part in 58,333 parts. The English degree is one grain per gallon of 70,000 grains. In the United States waters containing up to 10 grains of hardening impurities per gallon are considered soft; 10 to 20 grains per gallon, moderately hard, and above 25 grains per gallon, very hard.

### SCALE HARMFUL IN SEVERAL WAYS

When hard water is fed continually into a boiler, naturally the precipitated matter accumulates and in time produces a heavy scale or crust which settles on the tubes. This scale, being a poor conductor of heat as compared with iron, will increase the consumption of fuel many times. In addition, the iron, not being in direct contact with the water, is heated to a higher temperature and may become red hot, thus oxidizing more quickly on the outside next to the fire than when properly cooled by the water within. It also will displace the hydrogen from the water or steam on the inside, in time changing the iron on both sides to the brittle magnetic iron oxide.

If care be not taken to remove this scale before it

absence of pathogenic germs. Presence of chlorine and certain compounds of nitrogen are evidence of pollution by sewage. Examinations for the above mentioned impurities should be made by a sanitary chemist.

In order to determine whether a certain water is fit for domestic or industrial use, a complete analysis should be made. From such analysis it can be determined what treatment, if any, should be employed before the water is used.

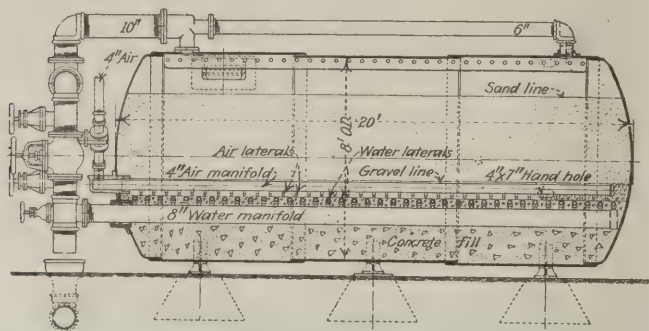

### TYPE OF ANALYSIS DEPENDS ON INTENDED USE

Water analyses may be divided into two parts: (1) Sanitary, physical and chemical, and (2) mineral. Under the head of sanitary analysis would come the physical examination of the sample to determine its turbidity, color, odor and taste; and under chemical analysis for the total residue, fixed solids, loss on ignition, free and albuminoid ammonia, certain nitrogen compounds, chlorine as chlorides, and oxygen consumed. When water is to be used for domestic purposes microscopical and bacteriological examinations also are made. The former consists of the enumeration of the kinds of microscopic organisms and an estimate of their quantity. It is used to indicate sewage contamination or pollution and often is helpful in explaining the chemical analysis and the

<sup>1</sup>"Standard Methods of Water Analysis," American Public Health Association, Boston, 1917.

presence of odors, color and taste. The bacteriological examination is made for the purpose of determining the presence or absence of certain harmful bacteria, more especially the B. coli group, to which reference already has been made. From these analyses the sanitary quality of the water is judged and its availability

Horizontal Pressure Filter

This air-agitation filter is constructed on the reverse-current-wash principle and is manufactured by the American Water Softener Co., of Philadelphia. The internal pressure in these filters may run up to 100 lb. or over.

for domestic consumption determined. The interpretation of a sanitary analysis is a matter of experience and as yet no hard and fast rules have been set down.<sup>2</sup>

It is not difficult to obtain a complete analysis which will show the incrusting and non-incrusting impurities. Before this analysis is attempted, however, the physical properties should be determined, and in the case of a turbid water it should be filtered and the analysis for mineral matter made on the filtered portion.

Domestic water may be purified in several ways: (a) By settlement (either naturally or by adding a coagulant such as alum); (b) by sunlight or by a chemical treatment with chlorine or ozone, all of which diminish bacterial life; or (c) by aeration, which expels objectionable odors, or again by sunlight, which decolorizes the water.

The water may be aerated by allowing it to fall over a cascade or dam. The water may then be filtered so as to decrease the turbidity. Coagulation is used to render a turbid water clear. It also effectively removes bacteria. Alum, in the proportion of one grain per gallon, is commonly used as a coagulant, being added before the water reaches the storage reservoir. When

Cost of Letting Scale Accumulate in Boilers

To obtain high boiler efficiency the flue-gas should leave the heating surface at as low a temperature as possible. Scale defeats this by preventing rapid conduction of heat from the flue-gas to the water. This curve, based on Prof. Schmidt's determinations at the University of Illinois, is published by courtesy of the Power Plant Specialty Co., of Chicago.

it is used relatively small ponds will serve for settlement. If the water is slightly hard crude alum alone is added, but if no lime salts (calcium salts) are present, lime is needed to assist in the coagulation.

<sup>2</sup>"Standard Methods of Water Analysis," American Public Health Association, loc. cit.

In many localities crude ferrous sulphate, a byproduct from cleaning iron, is used and is cheaper than alum. However lime also must be present in the water or be added to it. The lime precipitates ferrous hydroxide, which is easily and quickly oxidized to colloidal ferric hydroxide. This coagulates the suspended matter much the same as alum.

#### LIME TREATMENT FOR TEMPORARY HARDNESS

The temporary hardness of a water may be reduced by using slaked lime in the proper proportion, about 0.1 lb. per 1,000 gal. of water for each U. S. degree of hardness. This treatment may be applied to a water which is both turbid and temporarily hard. Filtering if properly conducted is efficient in removing turbidity and bacteria, and in many cases will decrease the discoloration. Filtration may be by either of two methods: (a) Slow sand filtration; (b) pressure or mechanical filtration. In using the slow sand method if the water is very turbid with an excess of algae it should be subjected to preliminary sedimentation or coagulation before it is admitted to the slow filter bed; this to prevent clogging and unnecessary cleaning and renewing of the sand bed. Mechanical filters are used after preliminary coagulation or coarse filtering. They are more rapid than slow filters, require less space, and are efficient when properly designed and controlled.

An added precaution often taken in treatment of water for domestic consumption as protection against bacteria is disinfection. Chlorine is used extensively for this purpose, the two most common forms being calcium hypochlorite  $\text{Ca}(\text{OCl})_2 \cdot \text{H}_2\text{O}$ , and liquid chlorine supplied in tanks under pressure. If the calcium salt is used it first must be emulsified with water and then continuously agitated while being fed to the water to be treated. Liquid chlorine necessitates special feeders which when once in operation require little attention.

In some instances water for drinking is boiled to insure its sterility, all pathogenic germs being killed by this method in less than five minutes. The taste of boiled water is not pleasant and may be improved by aeration, but this is likely to undo the effect of the boiling by recontaminating the water. Distilled water is perfectly safe, but from a physiological standpoint is not desirable for continued use.

The mine operator, from the standpoint of power development, is familiar with the great heat losses and the increased operating expense resulting from scale formation, corrosion and rusting. To these may be added other disadvantages less frequent but nevertheless troublesome and dangerous—namely, foaming and priming. When an untreated feed water is evaporated to steam in a boiler, all the impurities are left behind, and as the evaporation proceeds, the concentration of the scale-forming impurities increases until crystallization or precipitation takes place. The precipitated matter is the scale or sludge found in boilers. As has already been noted, the effects of scale are: (1) A reduced steaming capacity, and (2) overheating, with liability to explosion. The first effect results in fuel waste, the second is extremely dangerous.

#### MINERAL ANALYSIS FOR BOILER FEED WATER

The chemist bases his judgment of the value of a water for boiler use on the results of the mineral analysis, consideration being taken of the following points: Sulphates of calcium and magnesium are the

chief scale-forming impurities; the carbonates and bicarbonates of the same metals will be deposited as sludge and not as scale if the sulphates are low or absent, but if calcium sulphate be present even in small quantities it will tend to act as a cement and form a scale with the carbonates.

The treatment of boiler-feed water in general deals with the elimination of the scale- and sludge-forming impurities. Other materials usually found in water and considered harmless have been found by analysis in the boiler scale, proving that if sufficient cementing material be present they will add to the trouble. The chloride of magnesium, known to be an active corrosive agent, is a very soluble compound often found in natural waters. In dilute solution it has a very corrosive effect upon iron; the reaction appears to be catalytic, as the chloride of magnesium shows no diminution and no magnesium comes out of the solution.<sup>3</sup>

Large quantities of alkali carbonates as well as much organic matter may cause foaming and priming. Priming causes the steam to carry with it more or less water

methods: (1) The soda process, in which carbonate of soda or caustic soda is used to precipitate the sulphates of calcium and magnesium. Either the carbonate of soda or caustic soda may be used alone or in combination, depending upon the water. Caustic soda generally is used when the water contains much carbon dioxide. It is changed to carbonate of soda, which then reacts on the water to remove the remaining impurities. (2) The lime process, also known as Clarke's process—In this method, the necessary milk of lime or lime water is added to convert all the acid carbonates of lime (calcium) and magnesium into normal carbonates, in which form they are precipitated. In this treatment we have the curious paradox: "Add lime to remove lime." (3) The soda-lime process—This is a combination of the first two and the one most generally adopted. It is used on water that contains the sulphates of calcium and magnesium together with their bicarbonates or free carbonic acid, which combination will tend to render the soda process ineffective.

#### HEAT TREATMENT SATISFACTORY IN SOME CASES

Preheating the feed water, often referred to as the "heat treatment," is employed where the water contains carbonates of calcium and magnesium with free carbonic acid and no sulphates. The temperature to which water must be heated before it enters the boiler depends entirely upon the quantity of dissolved salts. Open-type heaters are used where the dissolved salts will precipitate out below 200 deg. F., these being the carbonates previously mentioned. In certain instances the sulphates have been removed from feed waters by preheating to nearly 300 deg. F., using live-steam heaters or economizers in which this high temperature can be maintained.

Many plants require for economy a combined chemical and heat treatment, heat being used to remove the temporary and chemicals to remove the permanent hardness. Commercial chemicals are employed in the chemical treatment, the more common being lime (containing 90 per cent CaO) and soda (58 per cent Na<sub>2</sub>O). Barium hydroxide, a byproduct of cement manufacture, is efficient in removing permanent hardness, but is relatively expensive compared with lime. Other compounds often used are barium chloride, barium carbonate, sodium oxalate and alums, all of which are more or less costly and used only in rare cases. It is desirable that all treatment of water take place before the water is fed into the boilers. There are times, however, when internal treatment is permissible, but it should not be undertaken without the advice of an expert.

#### CAN READILY DETERMINE LIME AND SODA NEEDED

Many methods have been devised for the rapid estimation of the quantity of lime and soda necessary for softening water.<sup>4</sup> The accompanying table has been calculated to show the quantity of soda or lime to be used in treating 1,000 gallons of water, each gallon containing one grain of the impurity noted, from which it is possible to calculate the quantity of chemicals necessary to use when the impurities are shown from a mineral analysis.

What is known as the "Permutit process" often is used in water-purification systems. Permutit is an artificial sodium silico-aluminate (Na Perm) supplied for use in the form of coarse sand. The calcium, etc., in the

**Permutit Type of Zeolite Water Softener**

Zeolite in the form of coarse sand removes such impurities as calcium, magnesium and iron by a chemical exchange. A treatment with common salt restores the zeolite to its original activity. It is claimed that this zeolite can be used over and over again for a period of twenty years.

in suspension, which, if it enters the engine cylinder, may cause a cylinder head blow-out. Where surface condensers are used and the water fed again to the boilers some effective means of separating the oil from the water should be used. This precaution is not necessary with turbines where oil is used only on the bearings and not fed into the steam.

Waters containing undesirable impurities may by several methods of treatment be rendered suitable for boiler use. The water may be treated chemically, in which case the impurities are precipitated, or by preheating, which results in the elimination of carbon dioxide and in the consequent reduction of the power of the water to hold certain salts in solution, thus precipitating the undesirable compounds. The heat treatment is of value only in treating temporarily hard waters. Chemical treatment must be used on those that are permanently hard. Should the water be turbid, carrying much suspended matter, it must be coagulated or filtered.

Feed water may be treated chemically by one of three

lowed to run to waste. Permutit is effective in removing iron, manganese, magnesium and other elements in the same way. The life of a charge is said to be over twenty years.

Simple tests may be made on a water to determine the presence or absence of injurious compounds by anyone with little or no knowledge of chemistry by following simple directions.<sup>5</sup>

Water treatment and purification, either for domestic or industrial use, should not be undertaken without

the advice of one familiar with such work. Avoid all secret preparations; they are either worthless or contain ordinary chemicals for which a higher price is charged under the name of a special preparation. In most cases it is a matter of chance that the compound is suited to the water.

Many large companies make a business of treating impure feed waters, and in the case of a bad water it is advisable to put the problem in the hands of these specialists. The importance of proper water treatment is shown by the extensive systems installed by many large industrial plants and municipalities and is one that deserves attention in isolated localities such as mining camps.

### Should Use Enough Coal on Washing Table for Perfect Stratification

**D**URING the past several months a study of the washability of fine sizes of coal on tables, with particular reference to Washington and Alaskan coals, has been conducted, in co-operation with the University of Washington, at the Seattle station of the Bureau of Mines. A coal from a Washington mine, presenting unusual washing difficulties, has been studied in considerable detail, using a particular commercial-size table. Float-and-sink tests of zonal products, supplemented by screen-sizing tests and chemical analyses, have given valuable information as to the workings of a coal table. This work is not yet completed but several conclusions of general application to any tabling operation may be drawn from the work to date.

There is a definite relationship between the tonnage of feed to a coal table and the maximum size of particles in the feed which will separate well on the table. The coarser the feed to the table, the greater must be the tonnage fed to obtain a good separation. A certain depth of material is required on the table to permit good stratification, this depth varying with the coarseness of the feed. On the other hand, there is an upper limit to the depth of material that can be separated on the table. These two factors will determine the maximum size that the table can handle.

The table used in the Bureau of Mines tests has a remarkable sizing action on all material that is properly stratified, that is, on all material that is not too coarse to stratify in the depth of coal on the table, and at the same time is not sufficiently fine to slime. The coarsest particles of any given specific gravity are discharged from the table first, and the finer the material the farther it will be carried out on the table before it is discharged. Materials of all specific gravities follow this same law. The result of this sizing action of the table is to make it impossible to obtain a clean separation between materials near in specific gravity when using an unsized feed. On the other hand, a separation using a classified feed will be favored by this action of the table.

The efficiency of the washing operation on tables is low when attempting to make a low-ash washed coal, and increases rapidly with higher allowable ash content in the washed coal. The explanation of this fact seems to lie in the fact that the largest proportion of the impurities is near in specific gravity to that of coal. The sizing action of the table previously mentioned causes an overlapping between material of different specific gravities, and the effect on the efficiency is more pronounced where the proportion is large.

<sup>5</sup>Coal Miners' Pocketbook, 1916, p. 428, McGraw-Hill Co., New York.

# Dividing the State of Pennsylvania Into Areas Having Coal of Equal Volatile Content

How These Areas Were Mapped—Their Form and the Reasons for It—Why Irregularities Exist and How Oil and Gas Are Found Only in Places Where Coal Contains Both

WITH A FEW exceptions the quantity of volatile matter in the coal of the Eastern half of the United States is determined by its geographical location. In consequence it is possible to draw lines that show where in the state the coal has a certain percentage of volatile matter. The lines so drawn are termed "isovols" from the Greek word *isos* and the English word volatile. These lines looking like contours separate areas of coal having a higher volatile content than those having a lower.

For several years the Pennsylvania Geological Survey has been co-operating with the U. S. Bureau of Mines in sampling and analyzing Pennsylvania coals. These analyses will be published later in bulletins of the Bureau of Mines. From the analyses thus collected it has been possible to construct a map showing the isovols of the State of Pennsylvania in greater detail than ever attained before.

It was originally intended to obtain and analyze samples of coal taken from every mine in the state, but inadequate appropriations seriously curtailed the work. For the most part, the samples taken were obtained by making a cut from roof to bottom, at a number of points in a coal seam, the impurities being rejected or included according to specifications furnished by the bureau. These samples, after being reduced by crushing and quartering in the customary manner, were packed in airtight cans for shipment to the laboratory where they were analyzed by the bureau engineers.

In addition to this, car samples were taken from coal shipped to Pittsburgh for testing purposes. Definite quantities of coal were taken from a car as it was being unloaded. The quantity taken was reduced to a convenient size, say about 50 lb., and this gross sample, being again reduced by crushing and quartering as before, the resulting sample was packed in airtight cans and sent to the laboratory for analysis.

## FOR SOME PARTS NEW ANALYSES NOT AVAILABLE

A third method employed was to analyze samples taken both at the mine and at points of delivery by persons not employees of the government. These, naturally, may vary in moisture and ash content, because of the drying out of the coal in transit or the inclusion of impurities loaded with the coal. For many outlying districts having no authoritative analyses, reports of the Second Pennsylvania Geological Survey and private companies were used. These analyses, of course, are less accurate than those made by the U. S. Bureau of Mines under ideal conditions.

In its routine of work, the Bureau of Mines had already analyzed a large number of commercial samples of coal taken for various departments of the government, particularly during war times. Many of these samples were shoveled from mine cars and the coal crushed and quartered before being shipped to the

laboratory in airtight cans. Other cars were sampled at their destination.

In compiling the isovol map shown in the accompanying figure approximately 1,500 analyses were made from samples of coal taken from 606 mines. These together with analyses of approximately 7,500 car samples, received from 75 mines throughout the state, were used as a basis, for determining the position of the isovol lines. Table I shows the number of mines sampled in each county:

Table I—Number of Samples Obtained for Drawing Map

Fayette.....	54		
			606

It should be explained here that, for the purpose of reducing the results of the analyses to a uniform basis, three forms were adopted: 1. Coal "as received" represents samples of coal received at the laboratory and assumed to represent the coal as it was cut in the mine, or taken out of the car as the case may be. 2. The "moisture-free" analysis represents the relative composition and heating value of dry coal and is used primarily for comparing similar coals of variable moisture content. 3. The "moisture-free and ash-free" analysis, known as the "pure-coal basis," represents approximately the relative composition and calorific value of the dry organic or combustible matter.

## MAP IS CONSTRUCTED "ON PURE COAL BASIS"

The percentage of volatile matter, on a "pure-coal basis," is obtained by the following formula:

$$\frac{\text{"As received" volatile matter}}{100 - (\text{ash} + \text{moisture})} = \frac{\text{Volatile matter in}}{\text{"pure coal"}}$$

In compiling the data for determining the position of the isovol lines on the map, the results of all the analyses were reduced to the pure-coal basis, although this is only an approximation; because ash does not have the same weight as the inorganic or incombustible matter in the coal. However, the maximum error is less than 1.5 per cent in comparing coals of about the same physical character and corresponding in ash-and-sulphur content. The greater the percentage of ash and sulphur, the greater the error in the pure-coal basis of rating.

Volatile matter on a "pure coal" basis is higher than on the "as received" basis which ordinarily is used in discussing the composition of coals. In coals having 20 per cent or less volatile matter on the "as received" basis, the volatile matter in the "pure coal" is approximately 1 per cent higher than in the coal on the former

basis and increases in direct ratio of 1 per cent to every 10 per cent of volatile matter on the "pure coal" basis.

Referring to the map, it will be readily recognized that the isovol lines there shown are necessarily generalized, although in the main they are accurate to a degree that is only limited by the lack of reliable samples in various localities. As would be expected, some analyses will appear anomalous, probably due to local variations of pressure in the folding of the strata. Naturally, such anomalies would have to be disregarded on a small-scale map.

The curtailment of the work for lack of adequate appropriations proved a serious handicap. In areas where the coal has been eroded, isovol lines are dotted and their position is more or less hypothetical, being based on the extent of folding and faulting in the district.

#### STATE HAS FEW COALS OF OVER 42.5 VOLATILE

Pennsylvania has few coals having in excess of 42.5 per cent of volatile matter. As indicated on the map, in small areas in the western part of Greene County and the southwestern corner of Washington County, together with a small area in the northwestern part of Washington, the southern part of Beaver County and the extreme western extremity of Allegheny County the volatile matter exceeds that percentage.

In general, however, the 42.5 isovol line marks the northwestern limits of the bituminous coal field in the state. Beyond this line to the northwest, only the lower beds of the Allegheny group and those of the Pottsville series are found, the overlying measures having been eroded. These lower beds cover but a small area, and their future value is negligible.

A careful study of the isovol map will show that Pennsylvania coals are generally and progressively less and less volatile from northwest to southeast. For example, the area containing coals ranging from 37.5 to 40 per cent of volatile matter, it will be observed, follow a general north-and-south direction along the valleys of the Monongahela and Allegheny Rivers to Redbank Creek, extending thence in a northeasterly direction in the vicinity of St. Marys and Coudersport. In the region of New Geneva and Lambertton, in Fayette County; Fredericktown and Millsboro, in Washington County; Herminie in Westmoreland County; Freeport, Johnetta, Manorville and Eddyville, in Armstrong County; and Summerville and Knoxdale in Jefferson County several small local areas have over 40 per cent of volatile matter.

In like manner, following the several isovol lines in regular order, the same gradual decrease in volatile matter continues in a southeasterly direction, till the Allegheny front is reached as indicated by the isovol showing 5 per cent of volatile matter, running through northern Schuylkill, southern Columbia, southern Luzerne and northern Carbon County is reached.

#### THEORIES OF ORIGIN AND FORMATION OF COAL

A brief reference to the origin and formation of coal will assist a clearer understanding of the isovol condition to which reference is here made. Recent work by Thiessen, Jeffrys, Turner and Randall on the microscopy of coals has proven conclusively their organic origin. Two general processes are responsible for the formation of coal. These are biochemical and the dynamo-chemical; the former referring to the

chemistry of organic life and the latter to the chemical agencies resulting from dynamic forces acting within the earth.

The former of these two processes does not carry the original organic matter farther than the formation of peat. On the other hand, the latter is the greatest factor in the alteration of the coal-forming material, involving changes both physical and chemical in their character. The action in the latter case is twofold, being the result of both heat and pressure incident to the movement of the strata in folding and faulting, causing gradual dehydration, whereby the volatile matter, including combined oxygen, hydrogen and nitrogen is progressively eliminated.

The origin of the dynamic forces that have resulted in mountain building and been accompanied with much folding and faulting of strata, in Pennsylvania, is generally attributed to an abnormal thrust that originated somewhere southeast of the state, its energy being dissipated in a generally fanshaped northwest direction. It is not commonly assumed that the action of this force was sudden, but rather that it extended over a long period of geologic time. However this may be the ultimate result was the upheaval of the Allegheny front, the effect extending northwesterly to the limits of severe folding in Fayette, Westmoreland, Indiana and Jefferson Counties.

The most anomalous variation in the gradual increase in volatile matter in the coal beds, from the Allegheny front northwesterly, occurs in the vicinity of Windber, in northern Somerset County, where the percentage of volatile matter is 15 per cent and less, though surrounded by areas ranging from 15 to 20 per cent. Though the cause of this local variation is unknown, it is Mr. Sisler's belief that beds of sandstone and limestone in the vicinity, by their greater resistance to the dynamic forces caused an undue devolatilization of the adjacent coal beds. David White believes that coal is more responsive to pressure than the enfolding strata, which would help to account for this local condition, which is found also at other local centers.

In southeastern Clearfield County, in the vicinity of Smoke Run and Osceola, the coals range from 20 to 22.5 per cent volatile matter, although surrounded by large areas of coal containing 22.5 to 25 per cent of the same. The rocks in eastern Clearfield County are much folded and faulted, though the faults are small, thrust faults predominating. The displacement here is generally less than 50 ft., vertically. Mr. Sisler's belief is that the areas low in volatile matter, in each of these cases, have been subjected to a greater pressure, because of the higher resistance of the adjacent rocks. In the latter case, however, the pressure has been somewhat relieved by numerous faults and the buckling of the beds.

#### RELATION OF OIL AND GAS TO COAL FORMATION

In a paper treating on the relations in origin between coal and petroleum, *Journal of the Washington Academy of Science*, Vol. 5, pp. 189-212, 1915, David White has advanced the theory that there is a direct relation between the rank of oils and the degree of alteration of carbonaceous deposits. He states that oils in regions and formations that have been altered but slightly by dynamic forces, are heavy and of low rank. On the other hand, regions that have been subjected to greater alteration, by dynamic influences, present oil of higher rank and lower specific gravity. Mr. White points out

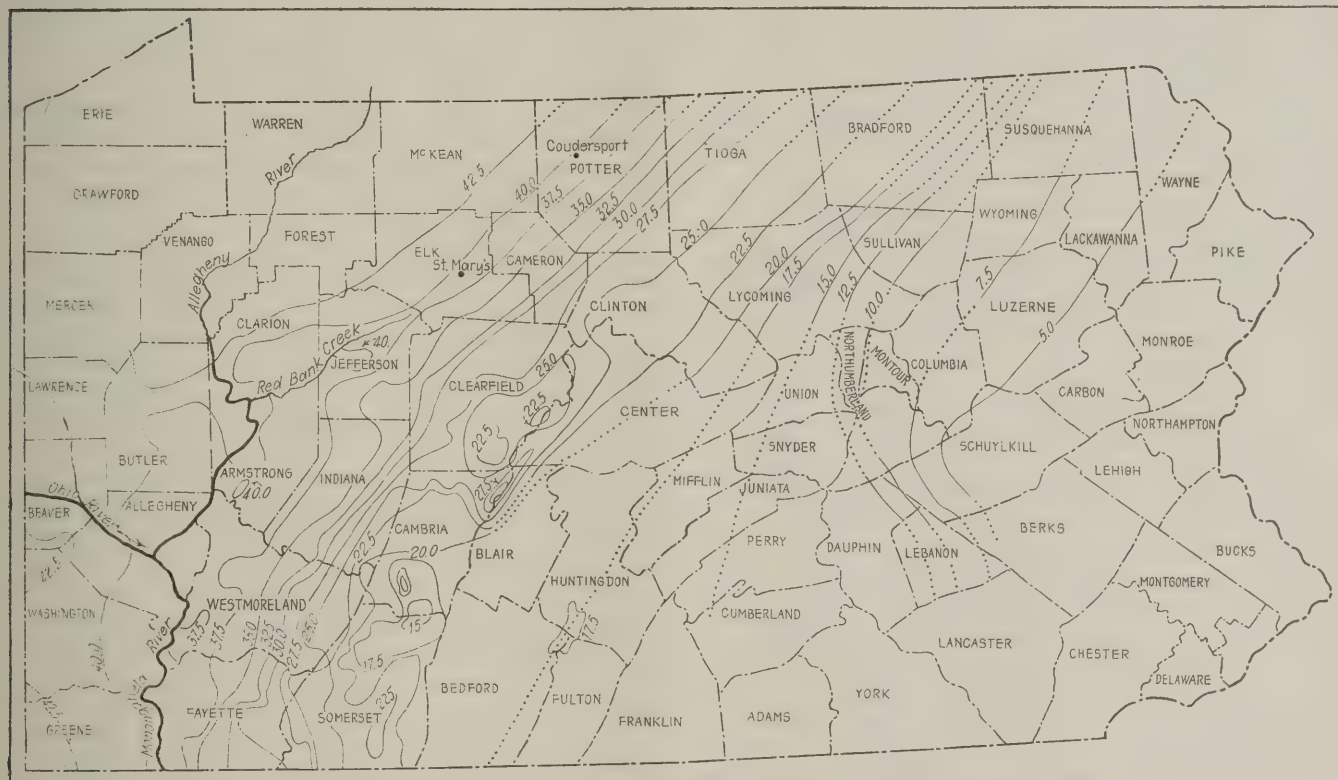

the fact that no pools of oil are present in rocks bearing coals having more than 65 per cent of fixed carbon, whereas in successive underlying formations, or in stratigraphically lower sands in the same formation, the oils are progressively higher in rank.

Applying these facts to the progressive devolatilization of the organic deposits in any formation, it is claimed that when the volatile matter has decreased to 30 or 35 per cent (pure-coal basis), in more provinces, commercial oil pools cannot be expected in that or any underlying formation, although commercial gas pools may occur in the border zone of higher carbonization.

In Greene, Washington and southern Allegheny Counties the oil pools lie on or west of the 40-isovol line, which cuts through the center of the gas fields in Greene, Washington and Allegheny Counties. In northern Allegheny, Butler and Armstrong Counties the oil pools lie on the 40-isovol line. In the northwest counties all of the oil pools lie west of the 42.5-isovol line. In Butler County, the gas fields are scattered, some of them being even west of the 42.5-isovol, whereas in Armstrong County the gas wells are east of that line.

The extensive gas pools of Greene and Jefferson Counties lie west of the 37.5-isovol, with the exception of

Map of Pennsylvania Showing Lines of Equal Devolatilization

In those sections where coal is absent, the direction of the lines is indicated by dots and has been roughly determined by a consideration of the probable stressing of the measures in the period of folding and from indications afforded by the nearest adjacent coal fields. The map was made

by using 1,500 analyses made of coal from 606 separate mines, spread somewhat evenly over the country. In some sections it was necessary, however, to take analyses made when the art was not standardized as at present and was not conducted as it is today. This introduces a slight inaccuracy which is unavoidable. The isovols, or lines of equal devolatilization, are in some places detached from the main lines and irregular. This is believed to be the result of unequal folding or of unequal resistance to rock pressures which caused a variation in the heat developed.

Table II, which is extracted from a paper by Myron L. Fuller, summarizes Mr. White's conclusions.

Table II—Relation of Volatile Matter (Pure-Coal Basis) to Oil and Gas Accumulation\*

Volatile Matter in Coal	Type of Oil Production
Under 30	Practically no oil and gas.
30 to 35	Small shows but no commercial production.
35 to 40	Isolated gas wells common, commercial oil pools rare, but of high rank.
40 to 45	Principal fields of light oil and gas of the world.
45 to 50	Principal fields of medium oil of Ohio, Indiana, and mid-continent.
Over 50	Fields of heavy Coastal Plain oils and of unconsolidated Tertiary or other formations.

\* Fuller, Myron L., Relation of Oil to Carbon Ratios of Pennsylvania Coals in North Texas; Economic Geology, Vol. XIV, pp. 536-42, November 1919.

#### OIL AND GAS POOLS IN PENNSYLVANIA

The hypotheses advanced by Mr. White hold true in the coal fields of Pennsylvania. The principal oil and gas pools lie west of the 35-isovol line. The principal oil pools lie west of or in the area containing coals having 40 per cent volatile matter. The 25-isovol line appears to be the eastern limit of the small commercial oil and gas pools.

a few near Punxsutawney, which lie between the 35- and 37.5-isovols. The gas fields of Forest, Elk, McKean and Potter Counties lie on or west of the 40-isovol. The Cameron gas field, which has not been extensively developed, lies on the 35-isovol, which appears to be the eastern limit of large commercial oil and gas pools. It may happen, however, that in areas east of this line where the alteration of organic material is great, some small wells may be found, but the oils will be light and of sporadic occurrence. Mr. Sisler suggests that wildcatting in eastern Pennsylvania should cease unless competent geologists or petroleum engineers consider the location favorable.

The percentage of volatile matter in coal affects its burning and so determines its suitability for various uses. The bituminous coals of Pennsylvania vary considerably in their composition and their adaptation to different uses. On this account, a coal must be chosen according to its type, if its use is to prove efficient.

The coals in northern Somerset County, particularly in the vicinity of Windber, and in Cambria Counties

are low-volatile, smokeless, steam coals. They are particularly valuable for railroad use and bunker fuel, besides being in great demand for domestic use. An excellent smithing coal occurs in the vicinity of Friedens, Somerset County, and in the vicinity of Lilly, Cambria County, these coals forming the upper Freeport seam. Lying to the east, the coals in the Broad-top field, in Bedford and Huntington Counties, average about 17½ per cent volatile matter and are highly prized for domestic fuel. Much of this coal is also used by the railroad and it has been coked with varying success, for many years.

#### COKING COALS VARY IN STRUCTURAL STRENGTH

Turning again to the west, the coals in the Johnstown region are mixed with other coals for coking. The coals on Black Lick Creek further west, in Indiana County, have been coked with much success as well as those in the vicinity of Bennington. The coals of eastern Westmoreland and Fayette Counties are used entirely for steam and domestic purposes, and those of the Connellsville basin, occupying the center of these two counties, have long been known as the Pittsburgh coking coal, from which high-grade coke has been produced for many years.

The coke from this district is unexcelled and has been used in blast furnaces since 1841. It is probable that this area of coking coal extends southwestward into Greene County, where the Pittsburgh bed lies under deep cover and has yet to be tested. The western portion of these two counties, together with northern Greene and southeastern Washington counties, form a typical gas-coal district. The coal in this area is particularly suited for making illuminating gas and is used extensively in the manufacture of byproduct coke.

Passing now to the north, the coals of northern Cambria County, Clearfield, Jefferson, Cameron, Elk and Clinton counties, are typical steam coals. They have been coked locally for use in blast furnaces. Clearfield County includes the area underlaid by the long-famous Moshannon coal, which has been highly valued for steam and domestic purposes, the coal being of the so-called smokeless type. The coals of Indiana County, on the west, are now almost entirely used for steam purposes. Some plants are coking this coal, which will probably be more extensively coked when the typical coking coals of southwestern Pennsylvania have been exhausted. They will at least be valuable in the near future for mixing with other coals for coking.

#### ARMSTRONG'S AND CLARION'S COMING GAS COALS

On the south and west, the coals of Washington, Allegheny, Beaver, Mercer and Butler counties are almost entirely used for steam and domestic purposes. Though containing a large percentage of volatile matter, these coals are much in demand as railroad fuel and much of it is also shipped to the Lakes. The coals in Armstrong and Clarion counties are high-volatile gas coals. Though now being used chiefly for steam and domestic purposes, these coals will undoubtedly gain an unexcelled reputation as unusually high-grade gas coals within a few years when the Pittsburgh bed, in the Irwin basin, becomes exhausted. In areas where the coal is high in ash and sulphur, however, it will be necessary to install picking and washing machinery to eliminate these factors.

The great variety of Pennsylvania coals offers the purchaser a wide field of choice.

## The Miner's Torch

### A Case of Conscience

MANUFACTURERS of equipment always feel beholden to employees of mining companies who help them make a success of experimental installations and occasionally such gratitude finds expression in terms of rather substantial presents. Without question such gifts are proffered with the best of intention on the part of the manufacturer, but—

While I was still young in the mining game I once recommended the purchase of equipment to my superiors and finally almost against their better judgment they followed my advice. Although there had been little precedent available to back up my judgment I made definite promises about the results that could be expected from the equipment and pinned my faith to them. The results obtained in the beginning were far from satisfactory and it is possible they never would have been satisfactory but for my efforts. (This may sound like self applause but it is not so intended.) I had more at stake than anyone else and I conducted myself accordingly.

After all of the "kinks" had been straightened out the general manager of the company that had furnished the equipment sent me a check for \$100 just to show that the company appreciated the interest I had taken in its problem. I kept the check two days trying to convince myself that I had a perfect right to it and then decided that I had no right to accept it, and returned it. "No man can serve two masters" was the argument that I could not get around.

I often recall that little adventure and sometimes it seems to me that in returning the check I was too jealous of my honor, but more often I feel just the other way about it. Just now it has been brought back to mind by a bit of gossip that I picked up concerning a man who was associated with me at that time. He was much disgusted with my decision and derived no small amount of pleasure from telling my friends about the incident; he generally wound up by quoting Shakespeare to this effect: "Conscience does make cowards of us all."

We drifted apart and I had lost track of him. Today a salesman mentioned his name and when I told him that I had not been in touch with him for a number of years he talked to me for more than an hour about my friend's "rise and fall," as he expressed it.

I learned that he rose rapidly and for a time seemed destined to reach a high place; then faltered in his climb and shortly began to drop back down the ladder. For the last few years he has never remained in one position long and each time the change has meant a smaller salary. "And how do folks account for this change in his fortune," I asked. "They say," said the salesman, "he has always had his hands out behind, if you know what that means, and in spite of his recent experiences he has not yet learned his lesson."

Well it hasn't helped him to know that "Conscience does make cowards of us all." Wonder if he ever heard this one: "If the camel once gets his nose in the tent his body will soon follow."

Loading by "Dustpan" to Keep Down Dirt and Breakage Restricts Quantity—Varieties From Same Bed Parted and Analyzed Separately—Americans Favor Practice Here

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Americans who made the tour of British coal mines in connection with their attendance at the World Power Conference, at London, were impressed particularly in all the British fields with the care exercised to prevent breaking the coal. A degree of care is exercised that is entirely precluded in this country by high labor cost. Similar care is exercised to keep coal clean. In South Wales, for instance, there is universal use of a sort of exaggerated dustpan for loading coal in mine cars. The mine owners admit that the use of this "box," as it is called, restricts the amount of coal the men can load, but they explain that the use of regular shovels would result in dirt being dug up from the bottom.

South Wales continues to pay by the ton of "large" coal. At the tipple the coal passes over 1½-in. bars and is screened, weighed and recorded. One of the reasons why they use so little powder is the fact that they do not wish to break up the coal. Fortunately most British coal comes down easily. The desire to prevent breakage has become inborn. The British regard our mechanical trimmer as all but a criminal device. They are in no way interested in installing this "Yankee notion." They are convinced that their reputation in international trade is built largely on size. With the release of the Ruhr many Americans will not be surprised to see the competitive situation become such as to force the abandonment by the British of some of these practices which add to the cost of their coal.

### Separate Coal from Same Seam

Another practice which astounds visitors from the United States is the separation of coal coming from the same seam when there is a difference in its physical character. In Great Britain there frequently is a stratification within the seam such as is rarely encountered in the United States. The famous Barnsley bed, in Yorkshire and the Midlands, for instance, carries an extremely hard steam coal in one part of the seam and a much favored house coal in another. As this coal is loaded the steam coal is put in one car and the house coal in

another. The steam coal is dumped on one set of screens and the house coal on another. Pickers re-sort any lumps that may have been classified wrongly by the loaders underground. It is contended that the sorting adds very little to the cost of the coal, but does add very materially to the sales realization.

This rather common sharp difference of qualities in the seams has led to an interesting practice in sampling. We think of a coal seam as a homogeneous thing. Our approved method of sampling is to cut a channel through the seam from top to bottom and quarter the coal until the sample has reached a size that can be handled conveniently. In England, however, separate analysis are made for each layer composing the bed. They frequently reveal marked variations in the value of the coal. In one bed, for instance, this practice revealed that a coal which formerly was penalized because of its sulphur content was getting all of its sulphur from a narrow band in one part of the seam, which could be picked out easily. With that band removed the coal was marketable for metallurgical coke.

### Americans Favor Scheme

Some of the returning Americans think there might be some application of this practice to some of our coal seams. The suggestion will be made to the Bureau of Mines that some investigation be made.

The Americans found the British immensely interested in low-temperature carbonization. They are striving to attain a smokeless fireplace fuel which can be burned readily in the type of grate found in practically every room of a British residence. Byproduct coke and gas coke usually are not suitable. The best fuel to furnish the Britisher with his much-prized "cheery fire" is a coal only partly coked so that enough of the volatile content is left to produce the flame. This accounts for the intensive research in connection with low-temperature carbonization, where coking is not carried as far as in the byproduct oven.

This work also is being encouraged by the demand for motor spirit. The British are anxious to render them-

## Northwest Rate Changes Save from South Illinois Suspended Till Jan. 8

Investigation was ordered by the Interstate Commerce Commission Sept. 9 into new rates proposing to increase and reduce rates on coal from points in northern and central Illinois to points in Michigan, Minnesota, North and South Dakota and Wisconsin. The changes were to have become effective Sept. 10, but were suspended until Jan. 8, 1925, pending the result of the investigation.

The rates from southern Illinois, however, went into effect Sept. 10, as per schedule, incidentally causing much confusion. This leaves the other fields with a distinct advantage over the southern Illinois district. From the Linton field of southern Indiana, for instance, to the Twin Cities, the rate on lump coal is \$3.22 and on screenings \$3.05, while southern Illinois rates are \$3.75 and \$3.56.

selves less dependent on the outside world for motor fuel. Some of the low-temperature processes claim a larger yield of motor spirit than is obtainable as a result of byproduct methods. No less than six large semi-commercial plants are being operated on low-temperature processes. Another half dozen methods are in various stages of promotion, but have not reached the point of erecting an experimental plant.

In the opinion of the Americans who looked over the low-temperature situation a commercial success has been attained for no one of the processes. They do produce a fine coke which burns freely without smoke. Considerable amounts of tar and oils are recovered, but the recoveries are not sufficient to meet the capital charges.

The London Coke Committee, a co-operative body on which all the gas companies are represented, has succeeded in meeting the situation by designing an open grate which will burn gas coke. By introducing fluted channels in the grate and at the back of the fire box just enough draft is provided to burn this coke at the proper rate. As a result of this device, supplemented by attractive advertising, the London coke companies practically have solved the problem of finding a market for their coke and breeze. A portion of it, however, is being used successfully under boilers.

## Lewis Lambasts Stone For Not Paying Scale In Union-Owned Mines

The Coal River Collieries Co., which operates coal mines in West Virginia and Kentucky and is owned by members of the Brotherhood of Locomotive Engineers, is condemned by President Lewis, of the United Mine Workers, because it still refuses to sign a union scale agreement. The mines are shut down because they cannot break even by operating under union demands, according to Warren S. Stone, head of the locomotive engineers and chairman of the board of the coal company. Mr. Stone's statement was contained in correspondence over the situation, with Mr. Lewis, made public by the miners' head in Indianapolis Sept. 9. Since last April the mines have been closed.

In a letter to Mr. Stone, dated Aug. 23, Mr. Lewis states that the employees of the Coal River company have been engaged in a strike since April 1, and declares that the company has assumed the same attitude as other operators in the field attempting to force the union men to take a wage reduction. "The Coal River Collieries Co., while not a member of the Kanawha Coal Operators' Association and while not utilizing the eviction instrument, is in all other respects apparently co-operating with the coal operators. This is an intolerable position for a coal company whose stock is largely owned and whose affairs are directed by union men to occupy."

In reply, Mr. Stone said that the miners' union failed to carry out its agreement with his company while it was operated on a union basis and that his company desired to continue operations last April, offering to continue existing wages until an agreement was worked out and to pay the increase if one was decided on. His company, he said, suffered loss of large contracts by being forced to close when the men refused an offer. He declared the mines had been closed rather than operate non-union. Mr. Stone denied that the miners of his company are on strike, declaring that they are ready to return to work now.

Calling attention to aid given by his brotherhood to the miners' union in cases of need, Mr. Stone's letter continued: "The members of the Brotherhood of Locomotive Engineers, who have invested over \$3,000,000 in these properties, are entitled to some return on their investment. I think you will concede this, and yet at the present price at which coal is selling, and the cost of mining under the Jacksonville agreement, it is impossible for the union mines to break even." Under the Jacksonville agreement, he said, labor costs for loading a ton of coal were \$1.63 and the ton sells for only \$1.50.

In reply, Mr. Lewis denied that his union had broken any of its agreements with the collieries company. "Your company occupies no different position in this matter than any other of the thousands of coal companies which have agreements with our organization. The United Mine Workers cannot be responsible for problems of

## Utah Gives Brotherhood Mine a Black Eye

The State of Utah does not think any too well of the Coal River Collieries of Kentucky and West Virginia, owned largely by the Brotherhood of Locomotive Engineers, and operated by a company headed by the head of the engineers' union, Warren S. Stone. Utah's Public Utilities Commission has denied the application of the company for the right to sell \$100,000 worth of its securities in Utah. Secretary Hicks, of the commission, said the company is operating at a loss. The commission refused to have the property of the company examined or appraised.

management in which they have no voice. The question of efficient management and low-cost production to enable you to remain in the market with competing companies is one that must be dealt with by your corporation. It is a problem that forever confronts one who elects to become a coal operator."

Mr. Lewis ended his letter by demanding that the collieries company negotiate an agreement with the union on the basis of the Jacksonville agreement. To this letter Mr. Stone did not reply and the correspondence is ended with a telegram from Mr. Lewis to Mr. Stone on Sept. 3 again asking Mr. Stone to reply to the letter asking that his company make an agreement with the miners' union.

## Huff Quits Presidency of Victor-American Fuel Co. In Shake-Up of Officials

The Victor-American Fuel Co., in Colorado, has changed officers. On Sept. 9 it was announced in Denver that W. H. Huff, president; G. F. Bartlett, vice-president, and S. I. Heyn, secretary, had resigned. The affairs of the company are in the hands of J. C. Osgood, of New York, principal stockholder and chairman of the board. He becomes the new president. Ben W. Snodgrass, former general superintendent, is made vice-president and general manager, and C. C. Deiter, treasurer, also takes the secretaryship.

No reasons for the resignations were assigned in the announcement but Mr. Huff has been in bad health for a long time. Mr. Osgood, who went to Denver about a month ago, was quoted in the Denver papers as saying: "I will take over a large part of the work of the three men and the remainder will be divided up among the other officers of the company. There will be no change in the company's policy. I have been the real manager of the company all along and I am now merely taking over the active management."

The Victor-American Fuel Co. is one of the largest operating coal companies in Colorado, having mines in Las Animas, Huerfano, Fremont and Routt counties. No important property changes are contemplated.

## Pennsylvania to Buy Control Of Norfolk & Western

A move by the Pennsylvania R.R. to acquire control of the Norfolk & Western Ry. by the purchase of common stock instead of by lease, as indicated some months ago, is reported to be definitely under way. This is the first definite information concerning the plans of the Pennsylvania since the announcement during the summer that the two committees of the roads, formed to consider possible merger terms, had abandoned further meetings for two or three months.

Two propositions, both involving the purchase of the Norfolk & Western stock and the formation of a new coal company, were outlined. The first plan provides that payment for the stock be made in 6 per cent bonds, together with one-fifth of a share in the new coal company for every share of Norfolk & Western. The price of the Norfolk & Western shares would be \$150 each.

### May Accept Counter Proposition

The counter proposition included the payment of a 20 per cent dividend and a guarantee of 8 per cent of Norfolk & Western stock and one share in the new coal company for each share of Norfolk & Western now held.

Of the two propositions the latter was generally considered to be the one that would prove more acceptable to the Norfolk & Western stockholders. In either case the announcement is considered as putting an end to the vague rumors of a possible lease to be obtained by the Pennsylvania.

The new coal company, according to the announcement, would be formed to take care of large holdings of the Norfolk & Western in the Pocahontas coal region of Virginia and West Virginia and would probably also include some holdings of the Pennsylvania. At present the Norfolk & Western owns all the capital stock, except directors' qualifying shares, of the Pocahontas Coal & Coke Co. This company does not mine or sell coal, but makes leases on royalties to operating companies. About 178,000 acres of its lands and rights were being so leased on Dec. 31, 1922, the last figures available.

### Has Coal Holdings in Kentucky

Under agreement with various coal companies, the road operates lines into other coal sections of West Virginia, including Mingo County. Eleven hundred acres of coal land in Pike County, Kentucky, formerly leased by the Pond Creek By-Products colliery became the property of the Norfolk & Western in 1921, representing an investment of approximately \$370,562.

One reason believed likely to influence the purchase of the stock instead of the lease of the line by the Pennsylvania is seen in the fact that the Pennsylvania already owns a large block of the Norfolk & Western common. On Dec. 31, 1923, the par value of the stock amounted to \$38,757,700, and at the present selling price would represent an investment of nearly \$50,000,000.

## Strikers Suffering Some In Western Kentucky

With cold weather close at hand it is believed that there may be some breaks in the ranks of the union miners in sections of the western Kentucky field around Central City, where the strike has now been absolute over an area of about 20 square miles for nearly five months. So far there have been no breaks in the Central City territory, and miners took it as a joke when the companies tried to resume at reduced wages Aug. 25.

The Central City field has been organized for more than 25 years, and is firm in its belief in the union. Union benefits have been small, however, and unless increased, the workers won't be able to go very far into the winter. Eviction suits may be started in that section before long, as has been the case in the lower fields. Over the summer the miner can get along with his garden and small benefits, but the pinch of winter is different.

Already there has been some breaking into stores and stealing of food-stuffs. One operator recently had some of his own workers arrested, charged with storehouse robbing, which indicates that workers are getting more desperate.

The Norton Coal Mining Co., at Nortonville, recently reached an independent non-union agreement with workers and resumed operations. During the night of Sept. 4, four notices were posted about the camp, signed "Herrin," West Frankfort, Ill., "Muhlenburg," and "Indiana," these notices bearing "Quit Scabbing" in crude lettering, and amateurish drawings of coffins.

## July U. S. Soft-Coal Exports Largest of Year

Exports of bituminous coal from the United States during July, 1924, amounted to 1,630,849 gross tons, a notable increase over the 1,424,194 tons shipped during June, which had been the largest monthly shipment during the current year, according to the Coal Division of the Department of Commerce. Overseas exports amounting to 418,500 tons, against 317,325 tons in June, likewise were the largest of the year. Exports to Canada during July amounted to 1,202,400 tons, as compared with 1,096,467 tons in June, topping all other monthly shipments during 1924.

One of the reasons for increased overseas shipments in July was the heavier movement to Italy, totaling 115,055 tons, against 71,848 tons in June. Only during the past two months has any coal been exported to Germany during the present year, 3,743 tons being shipped in June and 8,227 tons in July. Of particular interest is the 5,542 tons of bituminous coal destined for Austria during July.

Exports to all countries of South America were the second largest monthly shipments during 1924, amounting to 39,098 tons, as compared with 84,302 tons during June. The 104,959 tons of coal shipped to Brazil

C. E. Lawall

Assistant professor of mining engineering in the University of West Virginia, who has been designated acting head of the department with the rank of associate professor. He succeeds A. C. Callen, now dean of mining at the University of Illinois.

during July represent a large increase over the 66,078 tons exported in June and take second place in monthly shipments to that country during the current year. To Argentina exports totaled 19,104 tons, also an increase over the June shipments, and while there were no exports to Uruguay during June, 5,014 tons were shipped during July.

Two unusual features of the exports during July were shipments of 5,745 tons to the Philippine Islands and 6,590 tons to British Oceania.

Exports of anthracite during July totaled 290,097 tons, against 349,134 tons in June, Canada receiving 279,088 and 335,154 tons respectively in the two months. Coke exports amounting to 48,983 tons, against 48,238 in June, are the highest since March. Of the total coke exports, Canada received 40,438 tons in July compared with 39,691 tons in June.

## Lackawanna Not to Merge, Says Truesdale

William H. Truesdale, president of the Delaware, Lackawanna & Western R.R., denies that his road is involved in the merger plans of the Van Sweringen or will be part of any other system. "The Lackawanna is going into no system," he declared, when attention was drawn to the report that the continued strength of the stock reflected buying by Van Sweringen interests.

Mr. Truesdale was unwilling to make any statement in reference to the \$60,000,000 of Glen Alden Coal Co. bonds now held in the treasury of the Delaware, Lackawanna & Western. Recent rumor has it that these bonds were slated for distribution among stockholders of the road.

## Railroads Make New Record In Efficient Use of Coal

Railroads of the United States made a new record in the economical use of coal during June of this year, according to records of the Interstate Commerce Commission, following urging by the American Railway Association and the International Railway Fuel Association that greater care be exercised in the use of fuel.

Freight locomotives in road service consumed 135 lb. of coal per 1,000 gross ton-miles in June, 1924. The nearest approach to this record since statistics have been kept was 141 lb. in June, 1922. The fuel consumed per passenger car mile in June was 15.6 lb., as compared with the previous record of 15.8 lb., made in June, 1922.

The fuel consumption in June of this year was 11 lb. less per 1,000 gross ton-miles than in June, 1923. In the first six months of this year there was a reduction of 13 lb. of coal used per 1,000 gross ton-miles, making a total saving of approximately 3,371,500 tons of coal at an average price of \$3.17 per ton, meaning a saving of about \$10,688,000 for the six months' period.

In passenger service the first six months of the year showed a reduction from 19.2 to 17.7 lb. per train car-mile, resulting in a saving of about \$4,235,000 in cost of fuel. In the first six months of the year, therefore, the total saving resulting directly from fuel economy in both the freight and passenger services amounted to almost \$15,000,000.

This economy has been brought about largely through the concerted and persistent efforts of the railroads to impress upon their employees the importance of fuel economy. Men concerned with the handling and use of fuel have been educated through the medium of meetings, posters and the moving picture. Some roads have set up "bogies" and have checked performances against these standards set.

A number of other reasons have contributed to this increased fuel economy. The railroads have been gradually retiring from service the older locomotives and substituting for them improved and more efficient types. Also during the recent comparatively slack period, the roads naturally stored their older locomotives and kept in service their more efficient ones.

## Cash Balance in Coffers of Miners' Union Gains

The auditor's report of the International union, United Mine Workers, for the six months ending May 31 last shows that the income for this period was \$1,320,861; expenditures, \$867,325, leaving a balance on hand of \$1,630,557, which includes \$961,900 of Liberty bonds.

Dues and assessment yielded \$1,257,051 among the income items. Salaries and expenses consumed \$369,332, publication of the *Miners' Journal* cost \$79,565, attorney fees amounted to \$65,560 and Ellis Searles was paid \$10,897 for "publicity." The balance on hand exceeded the balance of Dec. 1, 1923, by \$443,536.

## Alberta Miners Again Refuse 12½ Per Cent Cut

Overtures for the settlement of the coal miners' strike which has been in effect now for four months in eastern British Columbia and the Province of Alberta were made recently by James Murdock, federal Minister of Labor, but were rejected. He proposed a 12½ per cent reduction. W. A. Sherman, president of District 18, United Mine Workers, speaking for the miners' conference committee, said that it had been concluded, after careful deliberation and consideration, that the basis for settlement proposed was unjust and "cannot be conceded by our organization, and such is our decision." Mr. Murdock's suggestion was that the strike be settled on the basis of one-eighth reduction of wages existing as at March 31 last.

Commenting on the attitude of the miners' officials the minister said: "I think they have not a proper regard for the rights and interests of the public in the matter. I asked them to submit a referendum vote to the striking miners, but they declined to do so and I think they should have done that."

Mr. Murdock observed that common above-ground labor at the mines was striking for 82c. an hour while the current or fair wage for such labor was established in the government's fair wage policy as 45c. an hour. Mining carpenters were asking for better than \$1 an hour while the current and fair wage for carpenters in various parts of Canada was 80c. an hour, running, of course, somewhat lower and in some cases a little higher. A similar comparison, he said, might be made with other classes of labor.

"One reason for my suggestion," said Mr. Murdock, "was that in the Central Competitive region, upon which the miners in this territory base their claim, the miners' day is eight hours from face to face while the day in District 18 is eight hours from bank to bank. That means that the total elapsed period in

## Illinois Central Places Big Coal-Car Order

An order for new equipment, which railroad circles estimate exceeded \$16,000,000 in value, has been placed by the Illinois Central R.R. This order was for 6,200 new freight cars, of which 4,000 are to be gondolas, and follows closely upon an order of the same railroad for twenty-five mountain-type locomotives.

The order for 6,200 freight cars was distributed as follows: 1,000 gondolas each with the General American Tank Car, the Pullman Car & Manufacturing and the Western Steel Car & Foundry companies; 500 gondolas each with the Mount Vernon Car & Manufacturing and the Ryan Car companies; 1,000 box cars with the Standard Steel Car Co. and 1,000 box and 200 stock cars with the American Car & Foundry Co.

which a miner in the Central Competitive field required to complete a day's work is at least nine hours, for the reason that there is one hour reduction for the lunch period in the middle of the day, and to this time should properly be added such time as was necessary for the miner in the Central Competitive field to go from bank to face and return from face to bank before and after completing his day's work.

"Personally I regret the attitude of the miners' committee and it is unfortunate and entirely unfair that these workmen should be engaged in a strike which has now lasted for four months for the purpose of insisting upon the retention of a war-time bonus which amounts to approximately \$1.17 per man per day. It is, I think, conceded that other classes of labor generally, farmers and business men, have been compelled to relinquish peak war-time bonuses."

## Matthew Addy Co. Goes Into Hands of Receiver

The Matthew Addy Co., Cincinnati, jobbers and brokers in iron, coal and coke, went into the hands of a receiver Sept. 11, dissension among officers and directors having defeated the efforts of a creditors' committee, which for three weeks had been working with a view to reorganizing the company.

"Frozen" assets and the uncertainty of pending litigation, for and against the company, in the state and federal courts, were blamed by attorneys for the company's present financial embarrassment.

The receivership proceedings were brought by the Old Dominion Coal, Iron & Coke Corporation, of Virginia, which charged it was a creditor for \$7,656.70 for coke sold and delivered. Through mutual agreement between the company and a committee representing a number of the larger creditors, John H. Dickerson, former president of the Business Men's Club of Cincinnati, was appointed receiver by Judge Stanley Struble, under \$10,000 bond.

The company, a \$600,000 corporation, is said to have done an annual business of several millions of dollars. The creditors' committee had been working harmoniously toward bringing about a reorganization of the company and to avoid the receivership proceedings. Internal dissension, however, made it impossible to work out an amicable agreement and it was decided at a joint meeting of creditors and officers and directors to allow the company to go into a receivership.

A preliminary audit of the books of the company, attorneys said, showed assets of approximately \$960,000, while its merchandise liabilities were approximately \$525,000. While the books of the company indicate that it was solvent, its actual solvency depended upon what it was able to realize from the sale of its coal and fluorspar properties and the outcome of the pending litigation, it was said.

## Output and Value of Coal from Alabama and Arkansas Mines in 1923

## Standardization Conference To Be Held at Meeting of American Mining Congress

A feature of the annual convention of the American Mining Congress, Sacramento, Cal., Sept. 29 to Oct. 4, will be the National Exposition of Mines and Industrial Equipment. Exhibits will be made by manufacturing concerns from all parts of the country and by the Bureau of Mines, California State Mining Bureau, and county mining organizations of California. The exhibits will include a demonstration of the mine rescue and safety work.

The Pacific Coast office of the Bureau of Mines will stage a demonstration of the effective work which the Bureau is doing in training miners in mine-rescue work and in carrying on a campaign of education for greater safety in mining. A complete cross-section of a mine will be built, which will enable spectators to see a demonstration of a mine explosion and the rescue crew going into the stokes and bringing out injured comrades. In the mine there will be displays of different types of mine equipment and adjoining the working demonstration will be displayed the newest safety devices.

There will be 100 exhibits of the latest types of labor-saving and cost-reducing mechanical equipment.

The program of the fifth national standardization conference, to be held in conjunction with the convention, will include reports on the progress of the Coal Mining Branch of the Standardization Division, American Mining Congress, Warren R. Roberts, national chairman, and of the Mining Correlating Committee, American Engineering Standards Committee, Dr. E. A. Holbrook, chairman. Committee reports by the Coal Mining Branch will include the following: "Underground Transportation," C. E. Watts, Berwind-White Coal Mining Co., chairman; "Mining and Loading Equipment," D. J. Carroll, Chicago, Wilmington & Franklin Coal Co., chairman; "Mine Drainage," Charles H. Matthews, Westinghouse Electric & Mfg., Co., chairman; "Mine Ventilation," C. H. Trik, Jeffrey Mfg. Co., chairman; "Outside Coal-Handling Equipment," James Needham, St. Paul Coal Co., chairman; "Power Equipment," F. L. Stone, General Electric Co., chairman; "Underground Power Transmission," A. B. Kiser, Pittsburgh Coal Co., chairman; "Mine Timbering," R. L. Adams, Old Ben Coal Corporation, chairman.

## Westmoreland Company Starts Big and Modern Mine

A large modern mine, planned for a daily output of 3,500 tons, is being opened up by the Westmoreland Coal Co., Irwin, Pa., in the last large tract of undeveloped Pittsburgh coal in Sewickley Township (Westmoreland County), a holding of 3,000 acres. Many of the details, such as the choice of equipment, are yet pending.

Work has commenced on a three-compartment hoisting shaft, inside dimensions 12 x 34 ft., which will be completely lined with concrete. This shaft, which will be 300 ft. deep, has already been sunk to a depth of 100 ft. Simultaneously with the sinking of the shaft a 12 x 15-ft. two-compartment slope with an upper deck for man travel and a lower deck for materials, has been driven a distance of 200 ft.; its total length will be 900 ft.

In addition to the tippie and other buildings outside construction work will include the erection of a modern mining town for housing all the men to be employed. This new mine will be in operation some time next year.

## C. C. & O. Approves Lease

Directors of the Carolina, Clinchfield & Ohio R.R. approved on Sept. 12 the signing of the joint lease with the Atlantic Coast Line and the Louisville & Nashville for 999 years, as revised by the Interstate Commerce Commission. The lease previously had been approved by the boards of directors of the Atlantic Coast Line and the Louisville & Nashville.

Apparently the Department of Justice has placed the entire controversy with regard to trade-association statistics in cold storage until after the election. While it is regarded as practically certain that the department will take no exception to the association which collects statistics of production and stocks, and communicates only aggregates to its members, it is thought certain that no statement with regard to trade associations will be forthcoming at this time. The strong stand taken by the American Federation of Labor opposing undue limitation of trade-association activities is expected to discourage any demagogic attacks on this type of business activity.

## Sproul Interests Absorb Three Independent Firms In New Anthracite Merger

Special to *Coal Age*

Scranton, Pa., Sept. 16—The Von Storch Collieries Co., the Legitts Creek colliery and the West Ridge colliery, three large independent producers with operations near this city, are to be consolidated to form a new anthracite coal company under the merger planned by former Governor William C. Sproul and a syndicate of financiers, it was learned from authentic sources today. Reports had it that the consolidation would be completed by October, but this was not confirmed by officials of the companies concerned, who said that the merger was now in process of negotiation.

Warren Acker, of Scranton, and associates are the owners of the Von Storch Collieries Co. The Legitts Creek Company is owned by J. P. Burton and Hartman, of New York, and the West Ridge colliery is owned by Frank M. Vandling and others, of this city. Miller-Lynch Company, of New York, and Brown Brothers, of Philadelphia, are handling the negotiations, it is stated.

## Alberta Coal Cannot Go East

Coal from the Province of Alberta will not be marketed in eastern Canada this winter. This announcement was made recently after a conference between Premier Greenfield, of Alberta; Charles Stewart, Minister of the Interior in the Dominion Government, and Sir Henry Thornton, president of the Canadian National Rys. Sir Henry Thornton was unable to meet the joint proposals of the province and the Dominion, contending that the freight charges the operators were prepared to meet, together with the assistance the federal subsidy would insure, were not sufficient to justify the number of cars necessary for the handling of the business, particularly as these cars were urgently required to move grain.

Sir Henry argued that the railway could not move the coal under \$9 a ton, though government experts declared that it could be transported for \$7 a ton. The Dominion Government's subsidy proposed to guarantee the railway against any loss on the \$7 rate. The latter was impossible in the opinion of the Canadian National Ry. and Sir Henry suggested that the boards representing the railway and the government get together with a view to ascertaining whose figures were correct. Subsequently Sir Henry was interviewed by coal operators at Drumheller, and to them he said that, even should the \$7 rate be made effective, the Eastern American coal interests would put up a big fight to retain their market. Why, he asked, could not Drumheller coal be sold in Montana, Oregon and Washington? He was told that what was wanted were steady customers in Ontario.

Rock-Dusting  
Car

This car with 5-hp. motor and blower has been built for the Westmoreland Coal Co., for use at its Critterion mine. It will be noted that it is built of steel and is of permanent rather than experimental construction.

## Practical Pointers For Electrical And Mechanical Men

### Electric Lights for Inside and Outside Service at the Mines

Voltage Drops Should Be Kept as Low as Possible So That Lamps  
May Operate Efficiently—Ways to Connect  
Lights to Three-Phase Systems

IN THE past few years the tendency has been more or less to standardize the voltage used for lighting service in and about mines, using the same voltage underground as on the surface. Something of course may be said in favor of standardization, but to use indiscriminately any equipment either above or below ground, without regard to the many different conditions prevailing, is not the way to obtain the best results, neither is it conducive to safety, especially in mining work. Underground lighting systems as a rule are subject to extremely onerous conditions. The chances of leakages and the possibility that fires will result therefrom, are much more numerous than with surface lighting.

When electric light was first introduced into coal mines, the generating plants usually were of small dimensions, and the voltage was low compared with what has become common practice today. One of the principal reasons for employing low pressure, was to guard against leakage, though on account of the inferior character of many of these earlier installations, the danger nevertheless was considerable, and minor outbreaks of fire often occurred. Improvements in wiring methods, equipment and insulation however, soon led to better practices, and engineers gained confidence and so were led to introduce higher voltages.

On the whole these installations despite their higher voltages were safer because, granted suitable insulation was provided, there was the advantage that the current employed varied inversely with the voltage, and therefore reduced the possibilities of heated connections—a frequent source of trouble in the earlier low-voltage lighting installations.

The old carbon-filament incandescent lamp required much more power per candlepower than incandescent lamps of modern type. The original carbon-filament lamps consumed anywhere from 3.5 to 4 watts per candlepower, consequently, when a 16-cp. lamp operated on a 50-volt circuit the current was quite large. In contradistinction the so-called half-watt lamp available today consumes only about one watt per candlepower.

In connection with low-voltage lighting, an important point which must be remembered in laying out an instal-

lation is that a comparatively small reduction in voltage causes a marked decrease of candlepower. A small increase in voltage will seriously overrun the rating and reduce the life of low-voltage lamps. Thus a reduction of two volts in the pressure of a 220-volt supply would result in a loss of about 0.8 cp. with a 25 cp. or 30-watt metallic-filament lamp. The same voltage reduction on a 110-volt circuit would reduce the candlepower by over 1.5, and a similar reduction in the pres-

allow a definite drop in volts between the point of supply and the lamps so that a cable of moderate size may be employed without causing undue loss of voltage at the point where the lamps are connected. Thus, assuming that 110 volts are required at the lamps, there is no reason why after calculating the current which will be required, the cable installed should not be of sufficient resistance to allow a reasonable drop of voltage along its length.

Alternating-current lighting systems are far more common today than direct-current, due to the extended use of alternating current for power purposes, which makes it convenient also to employ it for lighting. The use of transformers permits the tapping of power cables at points where lights are required and avoids the necessity for running long lengths of cables carrying

FIG. 1  
Without  
Neutral Wire

When the lamps are supplied from a Y-connected transformer without neutral wire, should the fuse in any wire blow, two-thirds of a previously balanced load will try to take power through the two remaining line wires.

sure of a 25-volt circuit would result in a loss of nearly 7 cp.

Thus the need for maintaining a constant pressure on a low-voltage lighting system will be appreciated. Moreover, from the foregoing figures it will be obvious that these circuits must be calculated from the source of supply to the last lamp if disappointment is to be avoided when a new installation is first lighted. The voltage of a generator supplying a small lighting system may be varied as required within certain limits, but alternating-current lighting circuits, which as a rule are tapped from the main power supply, have to operate at constant voltage, no variation being permissible beyond that provided by connections on the transformer. In this connection reference might be made to instances of low-voltage lighting where for some reason, the supply transformer is at some distance from the lamp.

Fortunately most groups of mine lights are controlled by one main switch, and therefore the load on the transmission line is constant. This being so, the circuit may be arranged to

low-voltage current. Alternating-current lighting for underground use is really more suitable—from an insulation standpoint—than direct current.

It is well known that the negative conductor of a supply has an attraction for moisture and the positive conductor repels it. This is why insulation breakdowns more often occur on the negative wire when it is not directly connected to ground. The advantage of alternating current is that neither conductor attracts moisture, and therefore both conductors can be kept more efficiently insulated. On the other hand, for a given voltage a shock from a direct-current circuit is actually of a lower potential than with alternating-current. Voltages are measured in root-mean-square values and therefore a nominal alternating-current voltage is only about 70 per cent its maximum voltage.

A shock from, say, a 220-volt alternating-current circuit would be more severe than from a direct-current circuit of 220 volts. However, when it comes to using comparatively very low voltages this disadvantage of alternat-

FIG. 2  
**With Neutral Wire**  
When the loads are connected between a line wire and a neutral with a perfectly balanced load the neutral wire carries no current to the transformer. If a fuse blows in any line wire only one-third of the lighting system is out of service.

ing-current which is deserving of consideration when the voltage of a lighting circuit reaches 220 or over, need not be taken into account.

If a lighting load represents a considerable proportion of the three-phase circuit from which it is drawn, the system must be balanced, so that the energy taken from each main of the high-tension supply is approximately the same. Consequently, it is necessary to install three-phase distributing lines and to balance the lights on the secondary side of the transformers. This may be done in a number of ways. Fig. 1, represents the connections of a three-phase transformer star-connected; the lamps being connected across the lines A, B, and C. The primary side of the transformer has been omitted to simplify the diagram. The first lamp should be connected between A and B, the next between B and C and the third between A and C; this sequence of connections being preserved throughout each lighting circuit.

If such a system has the same number of lights connected between each pair of wires A and B, B and C, and A and C, will be balanced. The currents in all three mains on the secondary as well as on the primary side of the transformer will be equal. There is however, one objection to this method in that, should, for instance, the fuse blow in main B, the lamps connected between A and C, will remain lighted with their usual brilliancy, and those connected between A and B and B and C will be in series across A and C as they will have no supply from B. The same, of course, applies in case a fuse should blow in mains A or C. The effect is to maintain every third light on the circuit at full brilliancy, while the others are merely glowing.

The drawbacks of a circuit such as that shown in Fig. 1 may be overcome by employing four wires; one each from wires A, B and C coming from the transformer, and one from the neutral point as shown in Fig. 2. The quantity of copper in the neutral will need only to be as large as that of the mains, because of the interactions of the three currents in the mains, which are displaced from each other by 120 deg. With this circuit, if a fuse blows, only those lights on the particular supply wire are affected, and if the lamps are consecutively connected from mains A, B and C throughout the system as indicated in Fig. 2, every third light only, will be affected.

If the lighting system is an extensive one, it might be conveniently split into

three separate circuits, each with one main and a neutral wire. In that case, of course, the blowing of a fuse would cut out completely a whole section. This is an obvious disadvantage compared with the systems shown in Fig. 1 and 2 in which the blowing of a fuse would not cause complete darkness in any section.

### Resistance for Testing And Charging

The accompanying sketch illustrates an arrangement of resistance tubes which is a substitute for the familiar

### Resistance Tubes Mounted On Wall

Carrying capacity and ohms resistance of the separate units should be such that a short-circuit of the test points or charging chips will not cause overheating.

lamp bank, now so often used when charging repaired cells of battery

### Lamp Rack at Bon Carbo Mine

Every man can take his own lamp here, as he goes through the check house on his way into the mine, and there is no delay. He returns the lamp to its place when he checks out in the afternoon. In the foreground we see C. R. Garrett, mine superintendent.

locomotives and also radio and automobile batteries.

This form of resistance has several advantages over the lamp bank. The chief reason why it has found favor is that it eliminates the trouble and high cost of replacing lamps. In most lamp-bank installations no method of locking is used and as a consequence the group of lamps often serves as a supply; sometimes even the sockets are removed, all resulting in considerable irritation to the mine electrician. Even if locked the lamp replacements will be frequent, for if used twenty-four hours per day the life of a tungsten lamp is but a few months at best.

Satisfactory resistance tubes can be purchased for approximately \$2.50 each, this being cheaper than sufficient sockets and lamps to provide an equivalent current capacity. The use of 275-ohm units having a capacity of 350 watts each tends to make the resistance foolproof. A single tube or all tubes can carelessly be left shorted across the line and no damage will result. When charging one- to three-cell batteries or testing low-resistance electrical equipment the outfit will supply approximately one ampere for each tube connected into the circuit.

### Here's a Lamp Rack That Saves Time

The business of checking out electric cap lamps to miners going into a mine in the morning and of checking in the lamps again in the evening is rather complicated at some coal mines. All sorts of schemes have been evolved but most of them consume time, because, in most cases, the lamps have to be handed out one by one through a window by one or two clerks. It is different at the Bon Carbo mine of the American Smelting and Refining Co., a few miles back in the hills from the company's big coke plant at Cokedale, Col. There, each man takes his own lamp. He can do it on the run.

A long pair of lamp racks was built on either side of a runway going through the check house near the mine mouth. As the batteries are charged, the lamps are put on this rack, as shown in the accompanying picture. When the miners go through the check house on their way to work, the lamps are so effectively spread out that there is no congestion to speak of and no time is lost over lamps. Each man takes his own.

## Book Reviews

### Pulverized Fuel

SO RAPID has been the progress in the United States of the use of pulverized fuel that we are prone to regard it as a practice devised and developed wholly in America. A little book on "Pulverized Fuel" by W. F. Goodrich may serve to correct that impression. The British, he claims, originated the idea, though he does not appear to have made any examination of American patents. However, we may concede that if he did he would probably only confirm his present conclusions. Nevertheless, it is clearly proved that it remained for the United States to bring the use of pulverized fuel to its present state of relative perfection. This is so clearly recognized by the author that pages 17-92 are given up to United States practice and indeed many other pages in other parts of the book, so that it may be said safely that Mr. Goodrich's volume will find favor in America as it furnishes adequate information about American practice. French and British practice—we use the author's own arrangement—is given secondary place.

#### GOODRICH NOT OVERSOLD

Mr. Goodrich is not to be regarded as an uncritical enthusiast, for he prefaces his book with the statement that "pulverized-fuel firing is not faultless" nor has "every problem in its successful and economic application been solved." He says however that "the principal defect—the emission of fine ash from the chimney—does not present an insuperable difficulty, nor is the discharge of dust from the chimney peculiar to this system of firing; it is in fact an all too common trouble, even with some of the most modern mechanical stokers."

He says in a chapter on the future of pulverized-fuel firing that "it has been suggested by some enthusiastic advocates in the United States that no other fuel or system of firing can compete with pulverized fuel and that existing systems must be quickly superseded. With this the author is not in agreement. There are reasons why under certain conditions and to meet particular requirements, coal will continue to be used on grates. For similar reasons it is extremely unlikely that pulverized fuel will supersede oil firing." We are not certain that Mr. Goodrich is correct, and perhaps this negative attitude, too common in Great Britain, may prevent rapid development in that country. We, in the United States, ride our hobbies energetically—a practice which makes for rapid progress.

The first patent, Mr. Goodrich tells us, was taken out in 1831 and Europe made many attempts to accomplish the objects desired, but wet fuel, poor refractories, incomplete mixing of air and fuel, imperfect pulverization and difficulties with slag seem to have retarded progress, though the Claude Bettington boiler achieved quite a measure of success.

The subjects treated in this little volume are Pulverized Fuel—its origin and history; United States practice; French and British practice, design of equipment and operation; fuels suitable for use in pulverized form and the future of pulverized fuel.

The coal operator should be interested in pulverized fuel systems because they are likely to extend further the use of fine coal. Its economies serve to make the use of the smaller sizes still more profitable and hasten the day when the larger sizes are used no longer for steam boilers. Mr. Goodrich's book is one of the Griffin series of Technological Handbooks and is distributed by J. B. Lippincott Co., of Philadelphia. It measures 5 x 8 in. and has 223 pages.

### The Coal Industry

"DEDICATED in the public interest to the coal industry" or better "dedicated to the public interest in the coal industry." A. T. Shurick has produced a well-rounded, fairly conceived book of a character long desired by the general public, entitled "The Coal Industry." It is not a mass of statistics except in the appendix, but a popular treatise covering a somewhat larger range than the report of the U. S. Coal Commission.

Mr. Shurick has done his work well. He describes the coal industry neither with panegyric or censure. He contents himself with being simply informative. Nothing in the 371 pages of this book suggests propaganda. It is, therefore, the better entitled to the public's favor and acceptance. If the average reader wants to get a clear idea of the industry as a whole he cannot do better than follow Mr. Shurick's review of it in this volume.

#### A FEW HISTORIC BEGINNINGS

A long series of precedents, however, require that the reviewer recite the points in the book reviewed with which he finds himself at issue, even though these shortcomings do not in any measureable way mar the book. We may say, therefore, that in the story of the early beginnings of coal mining, the "embryonic stage" as he terms it Mr. Shurick has passed over most of the states and regions, even of those areas regarding which records are fairly easy of access. In his discussion Mr. Shurick tells us the well-known and romantic story of the opening of the anthracite mines; he gives us details of the early exploitation of the Georges Creek fields and then shifts to West Virginia regarding which, however, he gives an extremely short and fragmentary history.

We are aware that it was his duty to be brief, but to pass over central and western Pennsylvania, Ohio, Illinois, Indiana, Iowa, the Rockies, Washington and Alabama, not to mention

other fields is to fail to cover the history of the beginnings of coal production adequately.

Mr. Shurick on page 54 says of the world-wide advances in mining in the nineteenth century: "The progress in this century, in terms of the results achieved in output, methods of mining, mechanical improvement, etc., relegates that of the preceding centuries to the accomplishments of a merely preparatory stage" and then adds "Certain refinements and improvements in the existing practice are to be anticipated in the course of time, but the succeeding generations will be engaged more in picking up and perfecting the loose ends left over from the sweeping changes of the nineteenth century, and there will never be a recurrence of the revolutionary developments of that time."

From these passages you would judge the author to be an old man with a natural regard for the developments that took place largely under his eye, but he is not. One cannot understand therefore why he belittles the century that has seen almost his entire labors or having seen such revolutionary changes since the beginning of the century has lost faith that there will be more like them. Since January, 1901, what truly remarkable advances have been made! Mr. Shurick might have accumulated a few dates that would have given him assurance as to the progress that has occurred since that time.

#### NO END TO LANE OF PROGRESS

We may add, also, that there is no sign that the industry has come to the end of the long lane. Mr. Shurick himself has given evidence that this gloomy prophesy of his slipped from his pen unawares, for he writes on page 131: "The civil engineer of today would not contemplate the possibility of moving a few hundred tons of dirt without the aid of machinery; what then can be said of an industry that hand shovels seven hundred million tons of coal a year?" Later he adds, "A more difficult problem will be the one of working out a method for the combined mining and loading of the coal. These successive steps suggest to the reader the ideal towards which the industry is striving—the mechanical extraction and transportation of coal from the working face to the railroad car on the surface with human agencies confined to installing, repairing and directing the machinery." He terms these revolutionary ideas and prophesies their accomplishment, yet this is the man who a few pages back said that the age of miracles was at an end, and that the revolutionary advances of the nineteenth century would never be equalled. Should Mr. Shurick live till January, 2001 we promise him that he will be ready to say about the twentieth century what he has said about the nineteenth, unless war and tumult interfere with progress.

The volume has four parts—The Coal Fields, Mining Methods, Distribution of the Coal Mined and Economic and Sociological Conditions. It measures 6 x 9 in., is bound in cloth and costs \$3.50 net. Its publishers are Little, Brown & Co., Boston, Mass.

# Production And the Market

## Growth of Strength in Bituminous-Coal Market Continues Unabated

Gradually but none the less surely the coal business is climbing out of the slough of despond in which it was buried for so long. Though there is nothing spectacular about the upward movement, neither are there the exasperating reactions that usually characterize that type of market. The price gains of the last few weeks not only are being firmly held but quotations continue to show an upward trend. Though resumption of operations at mines that have been idle have not been so numerous during the last week, production is increasing at those that are running, particularly the larger plants. The general revival of business has not developed the vigor expected by many enthusiastic prophets, the increases in many instances being little more than the seasonal fall gains, but more conservative observers take comfort in the belief that the more gradual upturn is certain to be more lasting.

### Railroads Placing Heavy Equipment Orders

One of the most encouraging recent developments is the large volume of orders for new equipment being placed by the railroads, the latest being one for 4,000 open tops by the Illinois Central. This follows closely on the heels of contracts for 1,000 gondolas each by the Chesapeake & Ohio and the Philadelphia & Reading.

Coal Age Index of spot prices of bituminous coal registered a further advance of one point during the week, standing on Sept. 15 at 167, the corresponding price for which is \$2.02, compared with 166 and \$2.01 respectively on Sept. 8.

There was a slight gain in activity at Hampton Roads last week, dumpings of coal for all accounts for the seven days ended Sept. 11 totaling 338,432 net tons, compared with 327,133 tons handled during the preceding week.

Movement to the lakes, on the other hand, declined, dumpings at Lake Erie ports during the week ended

Sept. 14, according to the Ore & Coal Exchange, being as follows: For cargo, 705,606 net tons; for fuel, 42,598 tons, compared with 850,865 and 47,228 tons respectively for the previous week.

Production of bituminous coal declined sharply during the week ended Sept. 6, when, according to the Geological Survey, 7,941,000 net tons was produced, a falling off of 778,000 tons from the week ended Aug. 30, when 8,719,000 tons was the yield, according to revised figures. The decline was due to the observance of Labor Day, so that the average daily output actually gained despite the decrease in total production. A number of

mines operated despite the holiday, the day rating as about one-quarter of a normal Monday. Anthracite output likewise receded, 1,451,000 net tons having been produced, compared with 1,837,000 tons during the previous week.

Increasing strength continues to pervade the anthracite market, orders steadily gaining in volume, though actual business is by no means keeping pace with inquiries. Stove leads the demand, as usual, followed by egg and nut, but pea is showing increased strength and the steam sizes are showing renewed signs of life. Prices are holding firmly.

### Estimates of Production

	(Net Tons)

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Prices Higher

The lively demand for lump and egg coal in certain of the Midwest fields has had the inevitable result: Prices are increasing. The Franklin County (Ill.) producers increased their lump, egg and large nuts 25c. this week, so that the 6-in. lump quotation is now \$3.50, egg is \$3.25 and No. 1 nut \$2.90. Saline County followed suit and is trying to get the same price. A few more mines of the region are opening. This is in spite of the fact that weather is warming up and screenings are moving sluggishly at \$1.50@1.75. There is, however, already a suggestion of car shortage in the southern Illinois field. This may maintain the new price. With cars widely scattered just now, with domestic demand exceedingly brisk and with dealers' stocks low in the face of rapid business, it is predicted by some that the region is going to develop car shortages about every two weeks the rest of the autumn.

Central Illinois and the Standard district near St. Louis are both feeling the domestic pick-up. Standard lump already has increased from \$2.35 to \$2.50 and a further jump to \$2.75 is expected if the cool weather holds out. Mt. Olive lump has not been able to pass the \$2.75 price maintained there for several weeks. However, it is strong at that. Nut coal and screenings are hard to move. Standard

screenings are now down to 90c.@\$1. Indiana production has increased a little but prices remain unchanged except for a slight depression of screenings quotations. West Kentucky coal is not getting in on the burst of domestic business in the West and Northwest but east Kentucky, in the Midwest markets, is doing fairly well at \$2.75 for lump though a shortage of flat-bottom cars is a distinct handicap. Prices have to be shaded 25c. in some cases to move the coal in hopper bottoms.

Smokeless coal from West Virginia in the Midwest feels the pick-up too. Lump and egg has moved up a quarter to \$3.75@4. Mine run has lifted its bottom price from \$1.75 to \$1.85 but the top remains steady at \$2. A great volume of this coal saturated the market during the summer.

A little cold wave at St. Louis after a spell of warm weather made the householder wake up and order coal. Orders are mostly for high-grade with a little intermediate grade and very little demand for the cheaper coals. Anthracite, smokeless and coke are moving fairly well. Most of the dealers have a good supply on hand. Wagonload steam picked up this week, but carload steam is slow. The demand is far below the supply. Country domestic is unusually good on account of the change in weather, and this is going to be the cause of higher prices as the result of a demand for lump everywhere. Country steam is quiet.

Index	1924			1923
	Sept. 15	Sept. 8	Aug. 30	Sept. 17
Index	167	166	164	202
Weighted average price	\$2.02	\$2.01	\$1.99	\$2.44

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

### Heavier All-Round Demand in Kentucky

Chilly weather throughout the Central States and extending well into the South, with light frosts on the night of Sept. 9 at Louisville, has brought about a lot of demand for coal, coming from domestic consumers, retailers and some industrial buyers. Railroad consumption is picking up a bit account of the usual fall increase in tonnage, while gas companies are using more fuel, and longer nights and heavier industrial loads are creating better demand from the power and lighting concerns. Domestic consumers who have been putting off their buying are now coming into the market heavily.

Both eastern and western Kentucky screenings are weaker, \$1 being fairly close to the top of the market for either field. Eastern Kentucky quotes 85c. to \$1, and western Kentucky, from 90c. to \$1 and slightly over. It is understood that some utility business is to be had at 85c., and that it is going to be filled at that figure.

Eastern Kentucky mines are quite busy in some sections, and it is said that additional train crews are being put on by the Louisville & Nashville R.R. in the Harlan, Hazard and Elkhorn sections, due to increased running time of mines generally and the fact that a number that were idle have recently resumed.

Peak prices on quotations range as high as \$3 by some eastern Kentucky operators on fine grades of block coal, but not many are asking over \$2.75, and there is not much movement at over \$2.50. It is believed in some circles, however, that best coal in both eastern and western Kentucky will be at \$3 before the end of the month.

### Northwest Comes to Life

A better movement of coal to the docks from lower lake ports and a continued firmness in prices characterize the market at Duluth. The anthracite market is strong, and the soft-coal market, while it has not as yet proven sensational, is gaining surely. Prices are firm but unchanged.

Shipments from the Head-of-the-Lakes docks were better in August than in July. In all 18,589 cars went out, as compared with 15,301 in July and 23,914 in August of last year. Dock receipts in August were 1,537,190 tons, of which 351,320 were hard coal and 1,185,870 were soft coal. Total receipts until Sept. 1 are 949,470 tons of hard coal and 4,099,843 tons of soft coal. The hard coal showed an increase over July for last month's receipts of 112,000 tons. For the season until Sept. 1 hard coal shows an increase of 35,152 tons and the bituminous coal a decrease of 2,878,316. It must be taken into consideration that this year started with 4,000,000 tons of coal on the docks whereas last year the docks were bare.

Wholesalers in Milwaukee are in better spirits because of a marked improvement in the volume of orders and consequent acceleration of the movement of fuel from their docks to local bins and to interior dealers. One of the larger dock companies reports orders more than 50 per cent improved over the immediate past.

Receipts of anthracite thus far in September total 25,221 tons and of bituminous coal 99,400 tons. The receipts in Milwaukee up to and including Aug. 31 total 497,223 tons of anthracite and 1,314,210 tons of bituminous coal. Last year the receipts for the same period were 601,462 tons of anthracite and 1,823,193 tons of bituminous coal. Such fluctuations are not unusual.

### Western Markets Active

Kansas coal is moving in steadily increasing volume, and inquiries from dealers are increasing daily. Oklahoma production, however, still is low, partly due to labor disputes and partly to a weak demand. Arkansas semi-anthracite lump is moving well, as householders and institutions begin to lay in their winter's supply, but it has not been necessary to reopen more mines to supply the demand. Screenings, produced in limited quantities, are moving readily. No changes in price have been announced.

A much better feeling pervades the Colorado market due to a noticeable increase both in working time and production. Orders for all sizes are coming in more steadily now and a heavy season is anticipated soon. According to the operators' reports, mines worked on an average of twenty hours last week with only 30 per cent of lost time attributable to "no market." This is 10 per cent less than for any week since May. Prices are unchanged since Sept. 1.

In Utah mines are making better time but are still below 50 per cent of full-time capacity. There is a slightly better demand for coal from industries, and the retail business is in good shape. "Business is better than it was a year ago and so are collections" is the report of practically all of the more important retailers in Salt Lake City. Retail prices are unsettled. The tendency is upward.

### Ohio Markets Brace Up

Cooler weather has helped enormously to brace up the Cincinnati market during the past ten days, putting life in the domestic list that has not been seen in months. Standing orders that have been suspended for weeks suddenly came to life, and while the advance in price was a little slow in some places, brokers and wholesalers who had supplies were able to hold firm on an immediate advance. Smokeless prepared sizes benefited perhaps more than any others. Low-volatile run of mine shows little betterment, but there is a heavier inquiry for screenings. With the upturn in price lake buyers show greater interest in bituminous. This has resulted in a little better position on 2 in. and 4 in., but egg is still inclined to drag. Practically no change has been made in retail prices.

A much better demand for domestic sizes has developed at Columbus. Retail prices are steady at former levels. Steam buying is restricted to immediate needs, but general industrial conditions are improving steadily and buying is expected soon. Some cheap coal is still available but demurrage cargoes are less numerous. Screenings continue strong despite the better output of lump. Lake trade is going along smoothly but the southern Ohio field is not sharing to any extent.

The Cleveland market shows no change—the healthier demand continues more or less in the steam trade, but, if anything, it is not quite so keen as it was a few weeks ago when screenings were 10c. a ton above present quotations. The retail trade, however, is active, but a large part of this trade is confined to smokeless fuels from Southern fields as well as domestic coals prepared in Ohio. Manufacturers and industries in general are laying by some fuel and current requirements are increasing with the improvement in general business conditions.

### Pittsburgh Market Stiffens

Production in the Pittsburgh district is now averaging above 40 per cent, having increased from less than 20 per cent in June, due to exhaustion of stocks and increased consumption. Further increase is looked for soon in domestic coal. Shipping in general is restricted to the area in which it has distinct freight advantages over the non-union fields, which greatly undersell it on the basis of f.o.b. mine prices. Prices have stiffened slightly.

Business at Buffalo is slightly better. Stockpiles have run down considerably. Slack has started up a trifle, gas slack especially, which usually is 10c. or so higher than steam. Quotations are \$2.25@\$2.50 for Youghiogheny gas lump, \$2@\$2.25 for Pittsburgh and No. 8 steam lump, \$1.75@\$2 for all mine run and \$1.10@\$1.35 for slack.

### New England Sees Improvement

Although there has not been any conspicuous expansion in sales, the New England tidewater bituminous market has developed a slightly firmer tendency in prices, \$5.35 gross ton on cars now being as low as is openly quoted for strictly pool 1 run of mine coal. Some business has been taken at \$5.25, but only where the business was particularly desirable.

Quotations for strictly navy standard coal at the southern loading piers have been fully maintained at \$4.10@\$4.20 gross ton, f.o.b. Norfolk although some tonnage of "good coal" has been offered at 5c. or so under this low figure. The spot market at Mystic Wharf has improved the past week in that although receipts have been fairly heavy, there has been less coal to dispose of after arrival and this has helped the price situation not a little.

The price situation at Providence also has improved. After some sales to clean up cargoes at \$5.30 on cars, \$5.35 is again the low quotation with some shippers firmly holding for \$5.40.

The all-rail phase of the market offers little new. New orders are practically nil. Wherever a price is quoted, it seems to be at the level that has obtained for many weeks, although so far as New England is concerned Pennsylvania coal is a matter of little interest.

### Atlantic Markets Picking Up Strength

Demand at New York is slowly improving. More orders are being received, but they fail to keep pace with inquiries. The latter are increasing rapidly. Large consumers are showing a desire to replace their reserves and not a few appear ready to close contracts extending to April 1 next. Business is quickening and operators and shippers are exceedingly optimistic. Local operators report some mines reopening, others being prepared for operation, while still others that have been working part time are extending their working schedule. There is a good demand for high-volatile coals and for slack, the latter being quoted around \$1.25.

The Philadelphia market is holding firmly the slight gains made during the past two or three weeks. The interest of the small consumer seems to be maintained and the occasional cars resulting represents about the entire increase in tonnage moved. There also is definite evidence of improvement in general industry. The railroads are increasing their orders, especially on contracts made earlier in the season.

A better line of inquiry is developing at Baltimore. It has not been pronounced enough to touch prices; as a matter of fact some sales were made last week even slightly below those of previous weeks. Despite rumors of a revival in the export situation the first eleven days of September show a falling off as compared with the same period of August.

### Anthracite Demand Gains Steadily

Demand for hard coal is increasing at New York, retailers reporting many new orders. Independent operators are easily disposing of output on about last week's price basis, much being sold at the maximum figures. Retail dealers throughout the Greater City last week followed the lead of the operators and advanced their prices, domestic coals ranging from \$14 to \$14.50. Stove is in strongest demand, though egg and nut are moving well. Pea coal is gaining strength and a large tonnage is handled in this market. The steam sizes are in better call. Rice coal is scarce with some producers, while barley is maintaining its strength.

The forward movement continues at Philadelphia. Retailers report that the consumer is ordering lightly, taking only one and two-ton lots. Producers seem to find a market for all sizes, as full time at the mines is now the rule. There has been no change in retail prices, although it is not thought that an increase will be much longer deferred.

Conditions at Baltimore are about seasonal. Following the Sept. 1 raise in price at both wholesale and retail there is a natural period of slow buying until cold weather is almost at hand. Yards are pretty well stocked and there will be no great difficulty in taking care of early demand at least.

Trade is setting in at a fair rate at Buffalo, buying now being much better. The supply is good, but it is not up to the demand for stove.

Toronto dealers have advanced prices from \$15 to \$15.50 per ton, explaining the increase as due to higher prices demanded by producers in the United States. The wholesale price has been rising at the rate of 10c. a ton for some time, but as the volume of business has been small the dealers had up to the present absorbed this increase.

Furnace coke contracting for fourth quarter at Connellsville is lagging. The spot market is quotable at \$3@\$3.10 as formerly, but most of the little tonnage that moves probably goes at \$3. Small lots sales have brought \$3.10 and occasionally in exceptional circumstances \$3.15. Foundry coke continues decidedly dull and there is some coke offered at under \$4, possibly not gradable up to standard. The market remains quotable at \$4@\$4.50.

# Foreign Market And Export News

## Prices Firm in Fair British Market; More Collieries Close

The steam-coal market in Wales is in a fairly favorable position and prices are firmly held, not on account of the number of orders but because available supplies have been materially decreased by the closing down of more collieries, especially in the Monmouthshire district. The other grades of coal are very irregular, and in every case supply exceeds demand. In most cases slight concessions are available for immediate shipment, but operators are holding present prices for forward quotations.

The steam-coal market in Newcastle is fluctuating and is generally weaker, though gas coals are in fair demand. The inquiry from Europe has revived somewhat. The Lithuanian State Railways have booked 60,000 tons of Yorkshire steams for April-September shipment, and the Swedish State Railways have been inquiring for 30,000 tons of best steams for September-December delivery.

Production by British collieries during the week ended Aug. 30, a cable to *Coal Age* states, was 5,113,000 tons, according to official reports. This compares with an output of 5,279,000 tons during the preceding week.

Total output in the first six months of 1924 was 139,062,000 tons, compared with 140,792,000 tons for the corresponding period of 1923.

Coal exports during the first six months of this year amounted to 31,131,000 tons, valued at £38,003,000. In addition to direct exports, 8,698,000 tons of coal was furnished to foreign shipping, making the total quantity shipped 39,829,000 tons, compared with total shipments in the first six months of 1923 of 48,927,000 tons.

### Hampton Roads Market Holds Fairly Steady

Little change is to be noted in business at Hampton Roads, bunker trade apparently contributing the bulk of business at the piers. The market is

fairly steady and the outlook somewhat better for increased movement.

Brazil and Italy are getting the bulk of foreign movement on contract with a limited number of shippers, but this movement is having little effect on the market. Accumulations at tidewater are slightly on the increase, and reports from the fields indicate a somewhat better production in anticipation of increase in trade.

The tone of the market is not strong, and forecasts of better business hold little hope of material improvement this month.

### French House Coal in Good Call, Moderate Industrial Demand

The French market is still quiet with only a moderate demand for industrial coals, owing to the slackening of activity in various industries. The sugar plants, however, have large requirements for coal, due to the promising outlook.

Up to now the Nord and Pas-de-Calais collieries have been helped little by the strikes in the Borinage coal field in Belgium, though they are shipping sizable tonnages toward the frontier region. Stocks, on the whole, are not very important.

The trend of sales in house coals is good. The Nord and Pas-de-Calais are establishing their price-list for October. Belgian producers are awaiting for the action of the French collieries to fix their prices accordingly.

Imports of British coals, which had dropped during the first two weeks of August, were larger during the second fortnight. The anthracite grades are nevertheless still too high in price at the shipping docks to attract the attention of buyers. Consequently, the inquiry is meager and few disposals are obtainable from the crushing plants in Rouen.

The Paris market is literally flooded with offerings of German coal for free sale, for which attractive rates are

quoted; for instance, 120 fr. per ton, at pit, for semi-bituminous nuts and cobbles. Even where the cost of transportation to Paris is added—about 66 fr. per ton—the rate is still sufficiently attractive to induce traders to buy.

Output of coal from the Sarre mines totaled 1,047,304 metric tons for the month of June last as against 1,164,904 tons during the month of January. The average daily production dropped from 703 kilogrammes per man in January to 693 kilogrammes per man in June.

## News Items From Field and Trade

### ALABAMA

The annual First-Aid meet in Birmingham will be held Oct. 7 at Rickwood Field. An interesting program is being prepared, which will be under the direction of the Alabama Mining Institute and local Bureau of Mines officials.

### COLORADO

The superintendents' club of the Colorado Fuel & Iron Co. held a fish fry at Stonewall, where the company maintains a summer place for its employees, on Saturday, Sept. 6.

### ILLINOIS

General Joseph B. Sanborn, 67, head of the J. B. Sanborn Co., a coal credit agency in Chicago, was married Sept. 4 in Chicago to Miss Willa Weck. General Sanborn served through the World War and has long been a well-known figure in the coal trade.

The Missouri Pacific R.R. is constructing a four-mile spur switch from Benton to Mine No. 1 of the Chicago, Wilmington & Franklin Coal Co., better known as Orient No. 1. The company expects to also extend the line to Orient No. 2 at a near date.

Now that Mine No. 9 of the Consolidated Coal Co. of St. Louis has been abandoned the famous Big Muddy coal is almost extinct. The only remaining mine in the Muddy field of seams No. 1 and No. 2 is mine No. 10 of the same company.

The Jewel Coal & Mining Co. has again reopened its No. 2 mine at Duquoin with prospects of operating steadily throughout the winter. The Gale Coal Co., which is the name of the new strip-mining company recently organized by the Crerar-Clinch interests of Chicago and located at Duquoin, also is running full capacity and within a few months will be producing a large tonnage daily.

According to a recent report of Mine Inspector Edward Flynn, of Perry County, the Paradise Coal & Coke Co. produced the greatest tonnage in his district in the last fiscal year, with a total of 384,048 tons. The Majestic Coal & Coke Co. was second with 354,496 tons, the Perry County Coal Co., third with 231,529 tons, and the Security Coal & Mining Co., fourth with 194,519 tons.

The ballot for the Illinois state miners' election in December is the longest in the history of the organization mainly because the last convention stripped President Frank Farrington

of much appointive power. Candidates for president against Farrington are John Hindmarsh, of Riverton, avowed radical, and William J. Sneed, of Herrin, sub-district president and state Senator.

Two first-aid teams of the Superior Coal Co. won first and second places in the big first-aid meet held at Gillespie on Labor Day. No. 10 team, captained by James Boston, won first with a perfect score, after a play-off with No. 13 team, under James Struthers, which had previously tied it. Third prize went to Team No. 4, Edward Daech, captain, from Maryville. Eighteen teams took part. Cash prizes amounted to \$920, each team receiving at least \$20. The meet was made possible through contributions by coal companies of the region, by citizens of Gillespie and by the United Mine Workers. It replaced the Illinois state meet, which was not held this year because of the failure of coal operators to support it financially.

### IOWA

A new coal mine, southeast of Colfax, known as the Hopkins City mine, will soon be in working order and mining operations begun.

### KANSAS

Two hundred Leavenworth coal miners who had been idle throughout the summer months went to work last week, according to an announcement by C. N. Fish, superintendent of the Home mines.

A move recently started to effect "100 per cent unionization" of District 14 by the United Mine Workers of the district has been halted to await a decision by the international board in regard to giving financial aid to non-union workers who quit open-shop mines to join the organization.

### KENTUCKY

The West Kentucky Coal Bureau, which has not met for a couple of months, was scheduled to resume meetings on Sept. 9.

J. C. Hanna, who has been manager at Louisville for the Scanlon Thompson Coal Co., has resigned to join the sales force of the Atlas Coal Co., Louisville. The Scanlon Thompson interests are installing a Godfrey conveyor and wooden hopper system for handling coal in the local yard.

The Kentucky state banking commission, blue sky department, has author-

ized the sale in Kentucky of a part of the \$13,000,000 of securities of the Old Ben Coal Corporation, of Illinois, under an agreement for financing with the National City Co., Chicago, in which twenty-year 6 per cent first-mortgage bonds and ten-year 7½-per cent debentures are to be sold.

The Empire Coal Co., Empire, recently suffered a fire loss amounting to about \$30,000.

It is reported from Middlesboro that the Congress mines have resumed after a shutdown of seven months, and that the Climax mines, which had been down for some weeks, would resume in ten days, while the Yellow Creek mines are putting on more men. This is due to a good demand from the South and Southeast and the fact that the union has become rather badly disorganized, and labor is now obtainable at a wage which enables the producers to enter competitive markets.

Upon reports that a radical element was replacing a conservative one, aiding striking coal miners in Webster County, Major William A. Clarke, Jr., assistant adjutant general, has ordered two National Guard officers to Providence, Ky., for observation duty. Reports of a tense situation have reached Major Clarke, he said.

The Kentucky Washed Coal Co., Nonell, near Drakesboro, operators of probably the largest strip mine in Western Kentucky, will resume operations in a few days, after being shut down for several months, as a result of clay sliding out from under the tippie wrecking that structure, last spring. A new tippie has been erected, and a temporary washing plant, which will be replaced with a highly modern jig plant before long. The plant has a capacity of 35 to 40 cars a day and operates in the Nos. 11 and 12 seams. W. J. Lester, prominent for some years as a strip operator in Illinois and other states, is president of the company. Arrangements have been made for the Harlan Coal Co., Louisville, jobbers, to sell the production of this plant.

Word from Harlan is to the effect that the Black Mountain Coal Corporation, operating one of the largest coal plants in the Harlan Field, after blowing its whistle each morning for a week to call the workers to the mines, and getting no response, has served notice on all of its workers to vacate company houses now occupied, and that legal possession will be taken, it being a case of work or vacate. The men refused a reduction in wages from the 1920 scale, in spite of the fact that

competing companies have generally reduced wages in that section. The company then closed down, and the mines have been idle since April. The new wage scale is being offered.

The new strip mine of the Dawson Daylight Coal Co., near Dawson Springs, which started operations in August, is running from 20 to 30 cars of coal daily and expects to increase that tonnage considerably as changes are made in equipment and arrangements, which will facilitate production. Removal of overburden also will be faster after the first cut is completed.

## MINNESOTA

The Minneapolis Civic and Commerce Association as well as most similar organizations in the Northwest, has issued a statement to the coal-buying public urging that coal be bought early to avoid interfering with the supply of cars for the grain movement.

A petition for receivership of the Reeves Co. has been filed by creditors. E. T. McDonald, Northwestern sales agent for the Philadelphia & Reading Coal & Iron Co., and G. H. Reeves, president of the Reeves Coal & Dock Co., Inc., were named as receivers. The Philadelphia & Reading claimed that the defendant owed \$43,000 with interest since Jan. 31, and \$58,000 due from Sept. 30 to Jan. 31, 1923. The Reeves company, while denying insolvency, did not fight the receivership.

## NEW YORK

Two young men opened an office at Buffalo recently and advertised to sell \$13 coal two hours for \$10. The attempt at fraud was so plain that they were arrested before business had fairly begun. One was discharged and the other was given a short penitentiary term.

## OHIO

There was closed in Cincinnati on Sept. 12 a contract for the delivery of 100,000 tons of Elkhorn coal for seaboard. It is understood that the seaboard prices were such as to make this business more attractive than the lakes or inland. It is said that this is the first large tonnage to move in that direction over the Chesapeake & Ohio for many months.

E. L. Douglass has accepted a position as vice-president of the Briar Hill

Coal Co. in charge of mining operations. He will have his headquarters at Crawford, Tenn. The Briar Hill company is financed by New York interests and owns and has under development some 40,000 acres at Crawford. Mr. Douglass, for many years, had charge of the operating department of the Jewett, Bigelow & Brooks mines in southeastern Kentucky. During the war he was Fuel Distributor for that territory for the government. He also was one of the vice-presidents of the National Coal Association. He was a co-receiver for the J. B. B. Co. when it was placed under the jurisdiction of the court.

## OKLAHOMA

Following a running fight Sunday, Sept. 7, between a motor-car load of attackers and state troops guarding the Kali-Inla mine, near Cambria, where sporadic clashes between union and non-union miners have been reported in recent weeks, additional national guardsmen have been ordered to the district by Adjutant General Baird H. Markham. No one was injured in this latest move against the mine, which is operating on an open-shop basis.

## PENNSYLVANIA

A strike of seven weeks' duration over alleged excess refuse in coal ended last week at the Weston colliery of the T. M. Dodson Coal Co., Hazleton, when 900 men went back.

Morris Lawrence, formerly chief chemist for the Hudson Coal Co. at Scranton, has left the employ of that company and is now engaged in practice in Scranton as a consulting chemical engineer with offices at 301-302 Mears Building. Mr. Lawrence, who is a graduate of Lehigh University in chemical engineering, will specialize on the chemical and research problems of the anthracite industry and in addition will carry on a general consulting chemical engineering practice.

John B. Gallagher, auditor for District No. 1, United Mine Workers, has issued a statement to the officers and members of all locals in the district warning against dual membership in the miners' union and in the organization sponsored by the Workers' party which has headquarters in Pittsburgh. The warning was prompted by reports of radical activities in the anthracite field, Mr. Gallagher said. John L.

Lewis, president of the Miners' International Union, is known to be in sympathy with the warning that has been sent out, having been active in a campaign against these alleged radicals in the miners' union for several years.

The Rochester & Pittsburgh Coal & Iron Co. has begun the shutting down of its stores and other accessories to its Adrian, Eleanora and Helvetia mines, which it announced a few weeks ago were to be abandoned indefinitely if the union miners would not agree to a reduction of wages. The towns and territory generally affected are trying by holding meetings and other means to avert a proceeding that promises to turn a prosperous Pennsylvania industrial district into a poverty-stricken neighborhood. The union refuses to yield and the operators claim that they cannot, if profit is to be expected.

Because of alleged irregularity in suspending a man named Grabosky, who had been serving in the capacity of checkweighman, for a period of two years after charges had been preferred, the charter of Nant-y-Glo local No. 1347, United Mine Workers, has in effect been suspended. Funds of the local have been tied up by order from the district headquarters. President Brophy stated that the charter was not formally suspended but that such action would be taken in the event Grabosky was not reinstated as his suspension was not in accordance with the rules. Mr. Brophy further states that the Nant-y-Glo organization had taken itself out of the union when it failed to pay its district tax. It was for this reason, Mr. Brophy said, that the funds were tied up pending a settlement.

## TENNESSEE

Miners who had been on strike at the mines of the Tennessee Coal, Iron & Railroad Co. at Whitewell for twenty-eight months have been ordered back to work by the local representative of the United Mine Workers. The first break in the long wage contest came when miners at Palmert and Soddy, in this territory, returned to work late in August under a compromise agreement.

## TEXAS

The Texas Power & Light Co., Dallas, is reported to have taken an option on 1,400 acres of land near Trinidad, containing lignite beds, and probably will build an electric power plant to consume the fuel on the ground.

## UTAH

The Columbia Steel Corporation expects to contract, within a few weeks, for the construction of 25 modern dwellings to be erected in its coal town of Columbia.

R. M. Magraw, of Hiawatha, general superintendent for the United States Fuel Co., has been made chairman of the Carbon County Taxpayers' Association. C. H. Stevenson, of Price, a coal retailer, is vice-chairman. The association, similar to many other taxpayers' organizations throughout the

Junior High School and Grade School at Hanna, Wyo.

One of the Union Pacific Co.'s mining towns. Hanna has nothing but mining on which to rely. Like most western coal-mining companies the Union Pacific takes a great pride in its schools. The nature of the soil makes it impossible to clothe the slopes and levels with verdure.

West, studies questions involving tax-exempt securities, limitation of levies and uniform accounting systems for corporations.

The Great Western Coal Mines Co., in which Jack Dempsey, heavyweight boxing champion, did not invest a cent although he was once heralded as owner, is preparing to mine coal in its property on Gordon Creek in Carbon County. It advertises that it will be able to start in October shipping domestic lump at \$4.85 f.o.b. cars at the mine. Stock sales in the company are said to be progressing and development work is advancing. Three miles of railroad grade have been built. Four miles more remain to be done.

Thomas A. Stroup, superintendent of the Clear Creek mines of the Utah Fuel Co., is running for County Commissioner of Carbon County on the Democratic ticket. He has lived in the county eight years. Previously, Mr. Stroup was with one of the big copper mining companies at Bingham, near Salt Lake City.

The drought of Utah, which has interfered somewhat with the water supplies of various mines, has become so severe since the cloudburst of mid-August—the only rain in the state since Memorial Day—that the head of the Mormon Church recommended that special supplication be made in churches on Sunday, Sept. 7, "for Divine assistance that the prevailing drought be broken."

B. W. Dyer, district engineer for the Bureau of Mines at Salt Lake City, went to Pittsburgh, Pa., for the Sept. 8 conference of Bureau field men. He expected to visit the Old Ben Coal Corporation mines in southern Illinois on his return. Much experimental work in rock dusting has been done there.

The Independent Coal & Coke Co., with headquarters in Salt Lake City and mines at Kenilworth, has filed a motion to dismiss the government's action which was to set aside certain land grants to the company on the ground that the land was of known mineral character before the patents were issued. The company holds that more than six years have elapsed since the issuance of the patents and therefore the action is barred by the statute of limitations.

## WASHINGTON

A report compiled by the Bureau of Mines shows that a total of 1,249,878 tons of coal was produced in 1923 from leased public lands of the United States located in various Western States. The ratio of growth of production is shown by the fact that in 1920 but 109,844 tons of coal was produced; in 1921 350,396 tons; in 1922 805,367 tons. The total production for the first quarter of 1924 amounted to 392,542 tons. Leased lands in Wyoming in 1923 yielded 546,519 tons; Utah, 211,300 tons; Colorado, 206,416 tons; Washington, 64,990 tons; New Mexico, 24,486 tons; Montana, 14,991 tons, and South Dakota, 197 tons.

## WEST VIRGINIA

An extra dividend of \$1 a share in addition to the regular quarterly dividend of \$2 a share has been declared on the common stock of the Island Creek Coal Co., payable Oct. 1, to stockholders of record Sept. 19. These dividends make total payments of \$12 a share on the common stock for the current year, as extra dividends of \$1 a share were paid in the previous quarters. The regular quarterly dividend of \$1.50 a share also was declared on the preferred stock payable Oct. 1, to stockholders of record Sept. 19.

A table prepared by the West Virginia Department of Mines shows that in coal produced in West Virginia in the fiscal year ending June 30, 1923, the Fairmount region led all others with a total output of 17,064,070 tons, the Pocahontas field ranking second with 16,724,010 tons. The table follows:

District	1923	1922
Panhandle.....	5,016,599	3,796,904
Fairmount.....	17,064,070	9,625,112
Preston-Barbour.....	6,694,430	3,066,657
Elk Garden.....	1,999,701	1,080,042
Mason.....	80,203	48,253
Putnam.....	365,047	170,552
Kanawha.....	9,812,000	6,110,150
New River.....	14,099,298	11,900,162
Logan.....	10,984,839	13,904,980
Pocahontas.....	16,724,010	18,354,975
Mingo.....	3,101,211	2,130,416
Small Mines.....	1,000,000	700,000
Totals.....	87,031,408	70,888,203

Having given notice to its employees that on Sept. 2 operations would be resumed at Osage Mines Nos. 1 and 2, on Scott's Run, Monongalia County, on the 1917 wage scale and employees having failed to report for work on that date, the Brady-Warner Coal Corporation has issued eviction notices which became effective on Sept. 11, according to the notice. There are 67 houses at the two Osage plants, 65 of them being occupied by union miners who have refused to accept the reduction in wages proposed by the company.

At the sale of the Gaymont mine, in Fayette County, the highest bid was \$600, notwithstanding the fact that the sale covered a leasehold of 1,000 acres of unworked coal at a 10c. royalty, a fully equipped, going mine, turning out a superior product. The Circuit Court of Fayette County at last accounts had not confirmed the sale. A further effort is being made by the special commissioner to find a buyer.

Progress is being made by the Pocahontas Fuel Co. in installing two large plants on its 30,000-acre lease, obtained from the Frick coal interests in Tazewell County, Va., and McDowell County, W. Va., on Jacobs Fork and Dry Fork, respectively. The cutting, cleaning and loading of coal is to be done by machinery.

The Hatfield Reliance Coal Co., of Cincinnati, proposes to build two piers equipped with coal-loading equipment at Huntington, according to plans on file in the office of the U. S. Engineers at Huntington. The company has for a number of years been shipping coal from its Kanawha mines by barge down the Kanawha River through Pt. Pleasant and from that point to Cincinnati

by the Ohio River. By building piers at Huntington and shipping by rail from the Kanawha field to Huntington—a much shorter distance than by water to Huntington—it will be possible to eliminate the long barge haul, using the river only from Huntington to Cincinnati. There is said to be no connection between the proposed construction of piers by the Hatfield Reliance Company and the Logan Coal & Dock Co., in which Philadelphia people are interested. The Philadelphia capitalists will ship their coal from the Guyan field to Huntington for transshipment to Cincinnati and other down-river markets.

## CANADA

John G. Quinn, mine manager at No. 5 and 6 mines at Comox, Canadian Collieries (D), Ltd., has resigned and will leave for New Zealand to take over the management of a colliery there.

The City Council of St. John, N. B., has had under consideration the dredging of the slip on the west side of St. John harbor occupied by the Colwell Coal Co. for some years. The facilities in the slip will be greatly improved for the handling of coal.

There is no indication of a settlement of the Crow's Nest and Alberta coal strike and a report is being circulated, which is without confirmation, that the Coal Creek Collieries are to be closed permanently and that an effort is to be made to open the Michel Mine regardless of the attitude of the United Mine Workers.

The coal trade has not been as brisk in the Vancouver Island field recently as it was in the month of July. With the exception of the Granby Colliery, Cassidy, and the Nanoose-Wellington Collieries, Lantzville, none of the island mines worked full time during August. There have been no signs of the improvement looked for as winter approaches.

Relieving in a certain measure the coal famine which threatens Alberta as a result of the deadlock between striking miners of District No. 18 and the operators, two mines in the Drumheller Valley are expected to resume operations immediately. It is understood that these Alberta mines have arrived at individual agreements. The mines in the carbon fields, many of which have not yet come within the scope of the United Mine Workers, are now producing more coal than they have for years.

The charter of the Westville local of the United Mine Workers, one of the strongest in Nova Scotia, has been withdrawn by the district executive, La Herly. This local has been entirely dominated by the radical element with Dan Livingston, deposed president of the district, and Alexander R. Stewart, deposed member of the International Board, controlling the situation. They have refused to pay their dues to the district or international organizations. Drastic action was advised by John L. Lewis, president of the International Union.

## Traffic

### Indiana Rate Discrepancies Being Adjusted

A supplementary tariff correcting increases on coal freight rates where reductions should have been made and granting the intrastate rates for shipments between two Indiana points when the route goes outside the state, is being prepared by the coal-carrying railroads of the state, according to George H. Mosser, managing director of the Indiana State Chamber of Commerce. Mosser said the coal rates in the schedule, which became effective Aug. 1 under an order of the Public Service Commission, bore many reductions, but had also increases between points not specified in the order issued by the commission. These discrepancies are being corrected.

## Recent Patents

**Mining Machine;** 1,489,583. Edmund C. Morgan, Chicago, Ill.; Olive E. Morgan executrix of Edmund C. Morgan, deceased. April 8, 1924. Filed Sept. 5, 1914; serial No. 860,369.

**Process for Carbonizing Coal;** 1,490,354. George W. Wallace, East St. Louis, Ill., and Arthur W. Warner, Media, Pa., assignors to the Wallace Coke, Oil & By-Products Co., East St. Louis, Mo. April 15, 1924. Filed Dec. 21, 1921; serial No. 523,910.

## Trade Literature

**Putting the Right Steel on the Job.** Taylor-Wharton Iron & Steel Co., High Bridge, N. J. Pp. 22; 5x8 in.; illustrated. Describes the many uses for Tisco steel.

**Thor Electric Drills.** Independent Pneumatic Tool Co., Chicago, Ill. Catalog No. 14. Pp. 25; 7½x10½ in.; illustrated. Electric drills and grinders, electric screwdrivers and electric drill stands are described.

**Centrifugal Pumps.** Morris Machine Works, Baldwinville, N. Y. Bulletin 122. Pp. 19; 8x10 in.; illustrated. Describes the construction and operating details of the Morris double-suction centrifugal pumps with horizontally split casing.

**The Celie Products Co.,** Chicago, Ill., recently published the following bulletins: **The Insulation of Boilers,** bulletin B-6e, describing in detail the method of insulating employed for various types and sizes of boilers; **The Insulation of Industrial Furnaces and Ovens,** bulletin B-8d.

**American Blower Co.,** Detroit, Mich., has issued Bulletin No. 1613 and Bulletin No. 1002, the former describing the **Ventura disc fans** and the latter the **Sirocco fans.** These bulletins are four-page folders and illustrated.

**Origin, Development, Results of Elesco** is the subject of a booklet published by The Superheater Co., of New York and Chicago. It gives a brief history of that company. Pp. 15; 3½x8½; illustrated.

**The Blacker Engineering Co.,** Grand Central Terminal, N. Y., has just published a new catalog describing the various types of blacksmith hammers manufactured by this concern.

**The Osgood Co.,** Marion, Ohio, has just issued a new circular, No. 245, featuring the application of traction wheels to railroad-type steam shovels. This new circular describes the various types of railroad and standard shovel equipment used in stripping operations and colliery yards.

Bulletin No. 390, describing roller bearings for mine cars, has just been published by the **Hyatt Roller Bearing Co.,** Newark, N. J. This book describes in detail the various types of bearings made by this

company applicable to coal mine cars. It also points out the advantages of roller bearings to increase transportation speed, reduce maintenance and upkeep charges and also effect power savings.

**The Oxweld Acetylene Co.,** Long Island City, N. Y., has just published a new 48-page catalog illustrating and describing in detail its extensive line of acetylene generators and oxyacetylene welding, cutting, lead-burning, heating and decarbonizing equipment. The book is full of information for the user, or prospective user, of oxyacetylene apparatus.

## New Companies

**The Tri-State Coal Co.** has been incorporated in Miami, Okla., with a capital of \$10,000, by Hobart L. Cheyne, W. B. Larimore and J. J. Stratton.

**The Rogers Elkhorn Coal Co.** has been incorporated in Virgie, Ky., with a capital stock of \$50,000, by T. T. Rogers and T. E. Rogers, of Virgie, and T. G. Rogers, of Greenville, Ky.

**The Jennie Wilson Coal Co.** has been organized in Owensboro, Ky., with headquarters at 326 W. 7th Street, Owensboro, with Jennie Wilson, president, and George S. Wilson, secretary. The company has 600 acres of coal land under development.

**The Sixty-Eight Mining Co.** has been chartered with a capital of 750 shares, no par value designated, to operate at Jacksonville, in the Hocking Valley district of Ohio. The property was obtained from the Central West Coal & Lumber Co. The incorporators are A. R. Jones, D. H. Armstrong, Elizabeth Voil, D. F. Shafer and F. E. Roth. Extensive improvements will be made to the property.

## Obituary

**William Scott Thomas,** well known in the coal industry in Schuylkill County, Pennsylvania, died in Philadelphia, Aug. 28, in his 79th year. He was born in Nova Scotia, removed to Schuylkill County when quite young and entered the employ of the Philadelphia & Reading Coal & Iron Co., becoming superintendent of the Mahanoy division. Subsequently he was engaged in the coal business under the name of Bright, Thomas & Co., the firm being known later as Donaldson & Thomas. He retired from active business in 1919.

## Coming Meetings

**West Virginia Coal Association.** White Sulphur Springs, Sept. 19. Secretary, W. H. Cunningham, Huntington, W. Va.

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3. Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**Alabama Mining Institute.** Annual meeting, Oct. 7, Hotel Hillman, Birmingham, Ala. Secretary, James L. Davidson, American Trust & Savings Bank Bldg., Birmingham, Ala.

**Illinois Coal Operators' Association.** Annual meeting, Oct. 7, Chicago, Ill. Secretary, C. E. McLaughlin, Fisher Bldg., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

**American Gas Association.** Sixth annual convention and exhibition, Steel Pier, Atlantic City, N. J., Oct. 13-17. Secretary, Alexander Forward, 342 Madison Ave., New York City.

**Canadian Institute of Mining and Metallurgy.** Sixth annual Western Meeting, Oct. 16-18, Blairmore, Alta., Can. Secretary, Moses Johnson, Blairmore, Alta., Can.

**Third National Exposition of Power and Mechanical Engineering.** Dec. 1-6, Grand Central Palace, New York City.

**Coal Mining Institute of America.** Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 909 Chamber of Commerce Bldg., Pittsburgh, Pa.

## New Equipment

### Bell with No Contacts

A transformer-type bell which has no contacts to cause sparking has been developed by W. R. Ostrander & Co., 371 Broadway, New York.

The bell requires only one watt to operate it and is therefore called a one-watt efficiency bell. It consists of a special laminated core and insulated coils mounted directly on a terminal board of bakelite. The armature has

Safe Bell for Mines

Because this little unit has no arcing contacts it is especially suitable for mine service. Neither moisture nor gas can make it dangerous.

no arcing contacts, and consequently the bell is safe for use in mines or other places containing explosive gases. When the armature operates it vibrates at a natural frequency of about 60 cycles and is adjustable. A cast-brass gong is mounted on the bottom of a frame which supports the transformer element. The standard rating of the bell is 12 volts.

### Starting Compensator Has a Time-Temperature Relay

A new automatic starting compensator for squirrel-cage induction motors will soon be placed on the market. This motor starter is for remote control of constant speed two- or three-phase squirrel-cage motors up to 600 volts for general applications such as driving line shafting, pumps, compressors, blowers, conveyors, etc. With it such equipments may be started or stopped from a distant point by means of one or more small hand-operated push buttons or snap switches located within convenient reach of the operator or automatically operated by a pressure governor, float switch, or thermostat.

The General Electric Co., which manufactures this compensator, has incorporated various new features. Definite and adjustable time acceleration is obtained by means of a new induction-type relay. Positive overload protection of the complete equipment is provided by a double-pole,

### Inclosed Motor Starter

Remote control apparatus makes it easy and safe to start any motor connected to this new compensator. A temperature relay combined with other protective devices prevents damage to the motor. In coal tipples and breakers push buttons may be placed at various points so that the motor may be quickly stopped in case of an emergency. It is always desirable that the operator be in a position where he can see the driven equipment before and during the acceleration period of the motor.

inverse time temperature overload relay. The starting and running magnetic contactors are mounted back-to-back in a sheet-steel inclosing case providing easy access to all parts. Several taps on the auto-transformer provide for adjusting the low voltage

to suit the starting requirements of different motor loads.

All parts are protected by the steel inclosing case and a conduit box at the back has several knock-outs and furnishes entrance for all power and control wires to the starter.

### Dampproofing Material for Concrete Surfaces

The Truscon Laboratories, Detroit, Mich., announce the placing on the market of a new product, known as Super Por-Seal. This material is a transparent dampproofing, intended for application over concrete, stucco, brick and masonry.

Most materials in this class in the past have been made of waxes, petroleum or other mineral-oil substances. The result is that even in the best of them, there was a slight tendency to stain the surface, due to oily nature of the compounds.

#### SEALS ALL MINUTE PORES

Super Por-Seal is a water-repellent compound for dampproofing. Its general composition is much the same as waterproofing paste, except that it is in a clear solution. It is absorbed into the pores of the stucco or masonry, where on evaporation of its volatile solvent it lines these pores with a highly water-repellent compound. Water thrown on such a surface runs off as freely as it would from a duck's back. Some interesting tests have been made of stucco surfaces, treated with only one coat of the material and stucco surfaces without any dampproofing. A bucket of water thrown on the untreated stucco surface immediately darkens the wall indicating water absorption. Water thrown on the treated

surface shows no darkening because it runs off immediately.

Such a material naturally is an excellent protective coating against moisture and frost for stucco, concrete, brick and stone. It doesn't darken or discolor the surface at all.

### Electric Drill Will Work in Concrete and Soft Stone

An electric hammer drill, suitable for drilling concrete and soft stone as well as for light chipping of metals, has

recently been developed by the Chicago Pneumatic Tool Co. It is equipped with a universal motor and will operate interchangeably on direct or alternating current. It is necessary merely to have the motor wound for the correct line voltage on which it is to operate.

The hammer blow delivered on the drill steel or chisel is the result of energy stored up by a rapidly moving piston which is mechanically free from the impelling force. The connection between the piston and the driving mechanism is by means of air which, at the instant the blow is delivered, restores energy to the piston through the expansion of the air which formed a cushion at the end of the upstroke. This means that there is no tendency for the electric wires or connections to be crystallized due to incessant jarring.

The essential details of the hammer are as follows: 1. Conveniently located inside trigger pistol grip switch of quick-acting type, so constructed to prevent starting of drill only by operator. 2. Terminal block for cable permitting cable replacement without disturbing other connections. 3. Adjustable brush rigging permitting of shifting brushes for perfect commutation. 4. Armature, drum wound. Heavily insulated coils carried in insulated slots in armature core. 5. Laminated stator structure having distributed pole-face windings. 6. Sheet-steel fan, carefully balanced and reinforced, providing thorough ventilation of motor. 7. Armature and all revolving parts mounted on high-grade ball bearings. 8. Crank gear. 9. Crank counterweight. 10. Connecting-rod. 11. Barrel. 12. Cylinder. 13. Piston.

The tool is well-balanced and when held loosely in the hand has the line of its center of gravity within the barrel of the tool and the operator's hand, thus causing the tool to hang vertically. A convenient trigger switch is located in the handle for the control of the electric current. The release of this switch opens the circuit, and the switch being inside the handle, the motor cannot be started accidentally by a blow from the outside. The bearings are all of the ball type, provision being made for lubrication of all revolving and reciprocating parts. All moving parts, including the gears, which are subject to wear, are hardened.

### Pneumatic-Electric Hammer Drill

Due to the serious vibrations set up in all types of hammers electrically operated, units must be carefully designed. This little drill delivers energy through the medium of air. The tool is well-balanced and may be started or stopped easily by means of a trigger switch.

## Long Way to Bottom Of World's Coal Bin

TO THE average person, that is, to the vast majority of those who make up what is usually termed the general public, two questions concerning coal are always pertinent. The first of these has to do with price—price now, next month, next year. The other is a vague uncertain apprehension, fostered more or less by writers of popular and semi-scientific fiction, that the world is burning up its supply of coal faster than it should and that within a comparatively short time, say a generation or two, the fuel bounty wherewith nature has so lavishly endowed this land of ours will have been exhausted and the peoples of that day and age will be compelled to seek some substitute means of heat supply or go cold and perhaps hungry as well.

As to the future trend of prices so many variables enter the equation that any attempt to forecast it can be little more than mere speculation. Certain it is that the extent to which labor-saving machinery is or can be adopted will play an important rôle in price determination.

Exhaustion of our coal resources is a possibility that is extremely remote. The period of time during which the world's known coal supply will be adequate to its requirements has been variously estimated by "experts" at from 500 to 15,000 years. This old planet, therefore, will not go cold for lack of fuel during the lives of men now living, nor within those of their children or their children's children. During 110 years of commercial coal production in the United States this country has exhausted, including losses incurred in mining, appreciably less than 2 per cent of its known coal deposits. Making all due allowance, therefore, for the increased demands of the future it is certain that our coal supply will last for "quite a spell."

## Yet There Are Compensations

WE SYMPATHIZE in the United States with our government-behounded British coal-mine operator cousin and we trust that our federal authorities will never so harass us to the disadvantage of the consumer, operator and miner alike. But there is a compensation. The British Government likes to see coal prices high because it means automatically much higher wages to the miners. It helps greatly with two million or so coal-miner votes. The women vote, of course, and their interest is the same as that of their men.

It is good indeed to have the government interested in high prices in your industry. The British Government chuckles when the operator gets a good price just as ours does when the farmer gets an increased return for wheat and corn. It must seem good to have the government with you when you boost your price and

look sad when you lower it. It's not so here unless you are a farmer. They coddle the farmer vote here just as they do the miner vote in Great Britain.

But then, and here's the rub, when the operator increases the "f.o.b. pit," the retailer raises his prices, which is, of course, to be deprecated. The government hounds the retailers for this offense. However, that attempt to shift the blame would not work if the consumer was properly organized like the miner. The government would take the snivelling retailer in hand just as Charlie Bryan did. It would establish coal depots on free non-taxpaying ground in the heart of the city. But the consumer really doesn't matter so much in Great Britain. He is poorly organized. He votes on large national issues.

The miner alone counts. He votes for himself, for his own wages and lets politics go at that. So the government is glad when coal prices rise, especially as about one hundred millions of tons, or over 33 per cent of the whole output, go abroad, and only one-third of the whole production is used for domestic purposes. When the foreigner pays who should care? He has no vote whatever and so is beyond the pale altogether and has no rights that anyone respects. No nation is really internationally minded.

## Union Mines Are Safe

IN THIS month's issue of the *United Mine Workers' Journal* is a cartoon entitled "He Changed His Tune," which is flavored, to say no more, with truth. A man is seen approaching a non-union mine, with a pick in hand, saying: "This is the life! The United Mine Workers can't tell me what to do." In the next picture, the man's pick is flying from the drift mouth in a manner suggesting an extremely violent explosion, and in the third the man, who is greatly frightened, is running from the mine pursued by a dog marked, "Accidents due to poor working conditions." By the way, the miner has had time meanwhile to put adhesive plaster on his face.

The flavor of truth in the story is that the union mines which do not work cannot well have accidents and therefore are safe. On the whole the working conditions are better in non-union than in union mines, some having wonderful records and many leading in protective devices, but the union mines are winning just now in the competition for safety, though not so much as the United Mine Workers would have us think. There are no accidents in industry when there is no industry to have accidents. The tin-mining industry in the United States has less accidents than that in Great Britain because in the former no one is employed in that industry. However, the automobiles at union mines are doing what mine accidents cannot do. When the mines are idle, there are more fatalities on the surface.

## What Foreign Trade Demands

**F**OREIGN commerce can be built up only on service. It is not possible to succeed if foreign trade is accorded less consideration than domestic. In fact, it is necessary to treat it with more care. The foreigner knows next to nothing about American coals, and Americans, knowing little about foreign boilers and firemen, cannot afford to dismiss the problem of distribution as cavalierly as they sometimes successfully do in this country. They must follow their fuel to the boiler room; they must note its behavior; they must ascertain what kind of coal will do the work best.

In this country a manufacturer who has had success with the low-volatile coal of one producer can find where there is another mine owner producing similar fuel. He can go to his dealer; he can ask his neighbors; he can consult a directory; he can look up the town on the map and seek another producer operating nearby or he can look in a trade paper and get some information—no matter how meager—from the advertisements it contains. Then there are the publications of the Bureau of Mines. His chances are one hundred times as good as those of a foreign buyer who, after much diligent but ill-directed inquiry, may get a gas coal in place of a low-volatile or vice versa. Success in coal selling abroad is based on service and mutual confidence.

Another necessity is a yard. Foreign buyers are often small consumers of coal. Besides, they, like others, do not like to buy a large shipment until they have tried out the coal. If foreign trade is to be built up the shipper must be prepared to deliver in almost any quantity. It is well to be able to give the buyer a chance to see the coal. It is partly because this element of success in selling has not been observed that so far we have been unsuccessful in placing coal in large quantities in Europe.

## Why Hunt Trouble?

**W**HEN buying new equipment why not make use of the expert knowledge of the manufacturer and at the same time automatically arrange the transaction so that the machinery being purchased is guaranteed to do the work required?

Too often the mining company having an elaborate engineering organization goes to unnecessary expense in preparing detailed specifications covering new equipment. Limiting dimensions and other essential details should of course be prepared with all possible care. However, most specifications should stop here, inviting the manufacturers to submit proposals covering a machine which will accomplish the desired result under the conditions set forth. Ordinarily the reliable manufacturer is only too glad to sell machinery on such a contract, accepting full responsibility for satisfactory performance.

Many times it has happened that a purchaser, who went to considerable trouble and expense in calculating and preparing elaborate specifications, found after installation that the new equipment was inadequate for the service intended. The manufacturer proves that he is not at fault because the machine conforms to the specifications which described the equipment but did not state the work to be performed. This sort of situation is about as unpleasant for the manufacturer

as it is for the purchaser. In most cases the maker, due to his knowledge and experience in his special line, could have furnished a satisfactory machine had he been given the proper latitude in the specifications.

When purchasing new equipment don't hunt for trouble. Include the necessary detail, putting it up to the manufacturer to supply a machine which will accomplish a definite purpose. On the other hand, avoid ordering duplications of old equipment that the manufacturer has discarded. This practice is neither fair to the makers of machinery nor to the purchaser. It cannot yield the best results. Spare parts cannot be as cheap if specially made and the company which gives an exact repeat order often finds its repair parts are more expensive and the efficiency of its equipment lower, though it gains, of course, in the quantity of spare parts carried, in not having in some cases to buy spare parts and also in the fact that its men know how to handle the old equipment and it would take time to accustom them to the new. The gains, however, are far less than the losses. In the interest of morale, no company should be buying new machinery of old type.

## "Keep Cool with"—Coal

**W**E HAVE only a few ways of keeping cool—all quite costly. One is to go out of town to the hills, the woods, the sea or the strand. Another is to take an automobile ride or a short excursion on the trolley. As George H. Cushing, speaking mainly of the moderately well-to-do, has well said, "it costs \$350 a month to keep cool; it costs about \$30 a month to keep warm." That is because we don't go about the business of keeping cool in the same way. We make our houses and offices warm; we do not make them cool. Who would not be happy to pay as little for reasonable coolness as for satisfactory heat? Too often we miss our calculation and go away in a cool spell to shiver and return to face blistering heat. But if we cooled our houses and offices we would make no mistakes of this kind; we would use our cooling apparatus when we needed it, even in the spring or autumn if the conditions warranted it.

The summer holidays are growing longer and "week-ends" are getting more numerous and time consuming. True, vacationing has its value. It clears the tired brain of cobwebs; it widens the scope of one's interest; it gives the children a relaxation they need; it affords an opportunity to cast off civilization just a little and go back to nature, but still it is getting to be a drain on business activity and, moreover, some cannot go, and in the still heat of city streets how greatly vitality is drained from those who have to stay at their desks!

In winter we have sometimes to raise the temperature of the air coming into our houses 60 to 90 deg. and in summer all we would need to lower the temperature would be 10 to 20 deg. The lowering may be inefficient as compared with the raising of temperature, but the range being so much less, the cost should not be excessive. This dissertation seems little germane to the subject of this publication, coal production, but the use of power to produce cold would level the peaks of coal consumption and the coal industry might do well to advocate the practice of the artificial cooling of houses, offices and places of public resort.

Kenilworth Rock Duster

## Rockies Are Full of Ingenious Dusting Machines

Lacking Perfected Apparatus, Mines Are "Rolling Their Own," Using Whatever Equipment Is at Hand—Uniform Feed Difficult to Assure—At Kenilworth, Hillside Dirt Is Blown on Freshly Watered Surfaces

**I**NGENUITY is having a full opportunity to do its work in the Rocky Mountain coal mines these days. The great problem "How to rock dust?" faces every mine superintendent, and it is no simple problem. But every man wants his mine made safe against the ignition of coal dust even if he is not driven to do it by law as in Utah. As a result the mountain region is full of home-made devices for applying inert dust of one kind or another and employing various principles. At Wattis, Utah, they are "mudizing" as described in a recent article. But most mines are blowing the dust in dry, using either adobe or native soil, ground or unground, or they are pulverizing shale or soft sandstone. One company tries soaking the entries first.

Nobody knows all about the art of rendering coal dust in a mine incombustible, but the men of the Rockies are finding out a great deal by the cut-and-try method, based on all the information available. Their greatest difficulty, just now, is to produce a dusting machine capable of applying the material as they think it ought to be applied. To meet this shortcoming they are inventing and adapting—and getting things done.

At Kenilworth, Utah, for instance, the men of the

Independent Coal & Coke Co. have built a unique machine and adopted a method all their own. Around Kenilworth, as at many other mines in the Utah Wasatches, there are thick outcrops of rock deposits which lend themselves well to rock dusting. The material is a sort of sandstone which disintegrates rapidly and completely under exposure to the weather. This dirt can be shoveled easily from the face of a bank through a sand screen and into a mine car and delivered into the mine as rather finely pulverized rock dust.

There is difficulty in stating exactly how fine it is, but judging it by its appearance and texture, a considerable portion would pass through a 200-mesh screen as most of it is finer than motor sand and crushes easily to talcum-powder fineness between the thumb and the forefinger. Recognizing this as a handy supply of rock dust, W. H. Woodhead, master mechanic; K. F. Lueder, mine foreman, and others of the mine force set to work building a machine under the direction of Superintendent W. F. Clark that would apply it.

They built a 1-yd. capacity bin of  $\frac{3}{8}$ -in. sheet steel welded at the joints in the form of an inverted pyramid. An ample outlet at the bottom of this bin feeds the dust down into a 12-in. pipe carrying the air discharge of a blower, an ingenious combination agitator and feeder preventing the dust from caking and delivering it to the outlet. The pipe is tapered so that the discharge is of only 8 in. diameter. Here a loose elbow may be revolved through an arc of about 45 deg.

NOTE—The rock-dust distributor in the headpiece was built for use in the Kenilworth, Utah, mines of the Independent Coal & Coke Co. mainly through the ingenuity of such men as Master Mechanic W. H. Woodhead (right), and Mine Foreman K. F. Lueder (left). It requires three men to operate it, including a motorman whose locomotive pushes the duster and its accompanying car of dust. The operator of the machine turns the discharge pipe about with the lever at the rear end of the car, as illustrated by Mr. Lueder, and the third man must shovel dust from the pit car into the hopper (posed by Fireboss Sam Westerfield).

**This Is an Example of New Mexican Ingenuity**

The new machine for blowing dry dust into manways, return aircourses and back entries in the Stag Canyon mines of the Phelps-Dodge Corporation at Dawson, New Mexico, consists of a 40-in. blower driven by an ordinary mining-machine motor. Dust is fed by gravity from a sheet-steel hopper into the discharge line which terminates in an elbow that has been cut in two to give the dust stream only a slightly upward direction. This unit is attached to a mine car carrying the dust supply, and the whole outfit is moved by a locomotive.

Of course, the men realized that the flow of dust from the hopper into the air stream must be uniform. It would not do to have the outlet at the bottom of the hopper so small as to cause packing or arching. Neither would it do to have the outlet so free that the dust flow would be too heavy for the air. And provision had to be made to prevent blowing back through the bin.

So along in the late summer they rigged up their feeding device, which was designed to overcome these difficulties and yet be simple and rugged. A section of 5-in. pipe suspended on an axle was set horizontally through the outlet aperture at the bottom of the hopper. Eight strips of  $\frac{1}{4}$ -in. flat steel  $1\frac{1}{2}$  in. wide were welded on edge to the outer surface of the pipe in parallel arrangement. This converted the pipe into a sort of paddle wheel, with the steel blades revolving through an arc which extended upward about 2 in. into the dust bin. The remainder of this combination agitator and feeder was enclosed in a cylindrical housing open at the bottom.

The dust fed by gravity into the spaces between blades, was revolved downward and dropped into the air pipe whence it was blown out through the elbow nozzle. The steel blades successfully prevented the dust in the bin from arching over the outlet. The housing in which the feeder revolved was of sufficiently snug fit to prevent much back pressure of air should the exhaust pipe be partially choked. The device provided also a uniformity of dust feed.

**Rock-Dust Barrier at Dawson, New Mexico**

This method of suspending V-troughs from crossbars is considered, by the Phelps-Dodge Corporation, as the best way to support barriers in the No. 6 mine of the Stag Canyon group. The roof is brushed high enough to erect 16-trough batteries, leaving a full 6 ft. of headroom. A battery covers the full width of the entry. Sixteen troughs when heaped have a capacity of 49.6 cu.ft. The dust used is tailings from a concentrator in the region. The roof and ribs are covered with wet adobe dust by a cement gun, even in the spots occupied by the barriers.

The upturned elbow at the discharge end of the pipe would revolve because the threaded joint was not screwed up tight. The dust stream could be directed from rib to rib at the will of an operator at the opposite end of the machine. An upright lever mounted close at his hand was connected with a rod running the full length of the machine and supported solidly on strap-iron rests equipped with plain bearings. Opposite the discharge end of the pipe this rod was bent downward in a right angle and connected, through an 18-in. steel link, to an arm projecting from a collar clamped firmly around the discharge elbow. By this lever and its connections, the elbow nozzle could be turned.

A 5-hp., direct-current motor, operating at 1,750 r.p.m., direct-connected to the 24-in. blower was also used to revolve the feeding device in the hopper. To do this, a 4-in. pulley was mounted on an extension of the fan shaft. A belt from this pulley to a 24-in.

**One of the Original Union Pacific Dusters**

This direct-connected blower in inverted position supplied the air and the small conical hopper supplied the dust which was discharged through the flexible-jointed pipe shown here in the hands of Supt. T. H. Butler of the Hanna, Wyo., mine of the company. The outfit was mounted on a mine-car track.

wheel accomplished one speed reduction. Further reduction was made by an 18-tooth pinion on the belt wheel shaft meshing with a 78-tooth gear on the shaft of the feeding device. Thus a speed of 67 r.p.m. was imparted to the feeder. All the gears and the motor were housed in sheet iron for safety.

About 100 ft. of light cable was used to connect the motor to a source of power. This cable was "hot-hooked" on the trolley wire as the outfit moved slowly along, or the end of the cable was clipped to the trolley wire and the clip moved from time to time as the machine advanced. The motor was grounded on the track through a truck axle.

When the machine first went into the mine it discharged the finely divided sandstone successfully, but not enough of it stuck to roof and ribs. The plan was then adopted of preceding the machine with a sprinkler hose. The entry in the process of dusting was thoroughly washed down immediately ahead of the machine, and the rock dust was sprayed onto surfaces saturated with water. The result was reasonably satisfactory. The sprinkler washed the coal dust to the floor, and the rock dust stuck to the surfaces in a sort of plaster coat. This "plaster" tended to let go its coarser particles

**A Booster Fan Does the Work Here**

This simple machine, which consists merely of a twelve-inch booster fan and a small wooden dust hopper from which dust is expected to slide by gravity through a curved pipe into the air stream, represents one stage of experimentation with the dusting problems at the Bon Carbo mine of the American Smelting & Refining Co., near Cokedale, Colo. Charles Smith, mine electrician, appears in the picture.

and presented, when fully dry, a rather dusty surface.

The machine distributed about two tons of dirt in completely dusting 1,000 ft. of 24-ft. entry which had an unusually high roof. The height sometimes ran up to 18 ft. The machine and an attached mine car of dust were handled by the hoisting rope on slopes and by a locomotive on main entries.

The machine was put into operation in August of the present year. There were distinct limiting features to this machine in its early stages, but some of these can be removed. The main difficulty was that it required too many men. When it was hauled by a locomotive a crew of four were required. One man sprinkled ahead, a motorman handled the locomotive, a shovelman stood in the mine car feeding dust steadily into the hopper and the machine operator directed the dust, started and stopped the fan and looked after the power cable.

When the outfit hooked onto a haulage cable on a slope, of course no motorman was necessary, but the hoistman should be accounted as part of the crew, for haulage on the rope was obviously impossible while the dusting was in progress. The shovelman could be eliminated only by increasing the size of the dust hopper, which would probably necessitate changing the feeding mechanism. But whatever its limitations, the machine represented one more idea in the long list which the West is developing. From experimentation with such ideas comes the finished machine of the future.

Another home-made dust distributor with many of the same limitations was that which was built in August at the Bon Carbo mine of the American Smelting & Refining Co., near Cokedale, Colo. It consisted of a wooden bin to hold about  $\frac{1}{2}$  yd. of dust. The feed was by gravity assisted by suction from the air line. The opening in the bottom of the bin was equipped with a pipe in the air line turned in the direction of the air travel. The necessary blast of air was supplied by a 12-in. booster fan blowing through a pipe which tapered to a diameter of about 3 in. at the outlet. This simple and compact outfit was mounted on a mine-car truck and was ready for travel into the mine, moved by a haulage locomotive and accompanied by a car loaded with dust. C. R. Garrett, mine superintendent, and Charles Smith, mine electrician, are devoting a good deal of thought to the machine in the hope of developing it.

In experimenting with this and that at the Delagua mine of the Victor-American Fuel Co., in Colorado, men used their ingenuity with whatever parts and equipment happened to be handy. The result was a blower made from a 10-ft. oblong steel tank and a low-pressure rotary blower capable of delivering a large volume of air. Holes were cut in the ends of the tank to permit a large sheet-iron pipe to be inserted the full length of it. The tank was filled with dust and slots in this pipe were made to admit the dust. The stream of air passing from the blower through this pipe was intended to produce such a volume of dust that a uniform deposit would be made throughout the area traversed.

Difficulty was experienced in getting a steady feed of dust through the inlet slots, and the outfit was cumbersome and heavy. But it represented a trail-blazing effort which has led the company into the use of more advanced dusting devices. The Victor-Ameri-

#### **This Is the Way They "Mudize" in Stag Canyon**

A cement gun is used by the Phelps-Dodge Corporation to apply tailings from a nearby mill or adobe dust from the ground surface or a mixture of cement and sand, one to eight. Wet tailings are sprayed on roof and ribs of all main haulage roads, the surfaces having already been gunited. The machine, with a crew of three men, can cover 600 ft. of such entry in a day. The train consists of the supply car, cement gun, air receiver, air compressor, water tank and locomotive.

#### Machine Planned to Produce Large Volume of Dust

It was built at the Delagua mine of the Victor-American Fuel Co. from various parts and old equipment which happened to be handy. The blower sent a stream of air through a sheet pipe running through a tank. Dust from the tank was expected to fall through slots in the pipe and thus be caught in the air and discharged in a cloud into the atmosphere without particular direction. Dust could be shoveled into the tank when a top lid was raised.

can Fuel Co. experimented with rock dusting at Delagua long before the rest of the country had waked up to the value of the practice. Its work began as far back as 1911 when General Superintendent Ben W. Snodgrass was superintendent there.

Experiments in building dusting machines have been steadily progressing in the mine shops of the Union Pacific Coal Co., at both Hanna and Reliance, Wyo. Such dusters as had been built by late summer were able to deliver the dust, but they, too, suffered handicaps that had to be overcome.

At Hanna, Superintendent T. H. Butler first tried an ordinary forge blower turned upside down and driven by a small direct-connected motor. This blew a stream of air through a 5-in. pipe on top of which was mounted a funnel-shaped dust hopper with a capacity of about  $\frac{1}{2}$  yd. A short piece of stout, flexible tubing connected the outlet with a 4-ft. length of galvanized iron pipe equipped with a hand hold. With this the dust could

#### One Motor Drives Everything on Kenilworth Car

By means of a belt and a reducing gear on the opposite side of the machine, a revolving feeding device, set in the bottom of the hopper delivers dust at uniform speed and without danger of choking into the 12-in. pipe from the blower. This pipe is tapered to an 8-in. discharge and connects with a loose elbow which can be turned from side to side by the operator. Roof and ribs are washed down with water immediately ahead of this machine so that the dust sticks to all surfaces readily.

be accurately directed by an operator. The whole unit was mounted on a truck and accompanied by a car of unground surface dust.

To control the flow of dust and to prevent a back-draught of air from blowing up through the little hopper, a 4-leaf, revolving valve built on the order of a stove-pipe damper, was installed in the round pipe through which the dust descended into the air stream. This was first turned with a hand crank so that a man had to walk along beside it to run the feed. This extra man may be eliminated by gearing or belting the rotary valve to the blower motor.

That company has experimentally dusted parts of its properties with adobe dust from the exterior of the mines, screening but not grinding it. Finally it has been concluded that fineness is obligatory, so a pulverizer has been installed.

The Phelps-Dodge Corporation at Dawson, New Mex., the Utah Fuel Co. and the United States Fuel Co., both in Utah, and several other companies have done much experimental work with dusting machines of their own construction. Thus the Rocky Mountain region has many hands and heads busy and the 1924 crop of dusting devices is proving itself a "bumper."

### Washing of Freeport Coals Studied At Pittsburgh Experiment Station

A study of the washing characteristics of coal from the thick Freeport bed in Pennsylvania has been completed by the U. S. Bureau of Mines investigators working in co-operation with the Carnegie Institute of Technology. The tests were conducted at the Pittsburgh experiment station. Coal from this thick bed makes good metallurgical coke except that at some mines the ash content is usually too high, and at other mines sulphur is present in the coal in excess of the quantity permitted in metallurgical coke. Therefore, washing to remove the ash and the sulphur is an important and vexing problem to the coal-mine operators. The coal is mined for byproduct coking, steam-raising, domestic use, gas-making and other purposes. The problem in washing is to eliminate the fragments that in mining get into the coal from impure bands present in the coal bed, as well as impurities finely distributed in the coal from some layers of the bed. It was determined that the best treatment for coal with bony fragments was to make three products—clean coal for coking, secondary coal for use in boiler plants, and refuse.

### Salt Damages Walls of Coke Ovens

Salt is an impurity which occurs in many varieties of British coking coals. It consists principally of sodium and potassium chlorides, and on account of its ultimate effect on the brickwork of the oven walls it is desirable to eliminate it as far as possible. To do this, frequent change of the washing water is necessary, as in course of time the accumulation of dissolved chlorides in the water becomes excessive, and instead of washing reducing the salt content of the coal it actually increases it. The washing water itself therefore must be as free as possible from these constituents. On account of its salty nature, mine water is frequently quite unsuitable for washing purposes. —G. Stanley Cooper in *Byproduct Coking*.

# Elaborate Care Fails to Protect Gates Mine

Pipes Extended to Face of Every Working Place—Electric Detonators a Possible Cause of Explosion—Many Safety Precautions Provided—Recommend Better Supervision of Night Shift

A COMMITTEE of mine inspectors composed of Edward E. Girod and four others have submitted a report of their findings and recommendations covering the explosion which occurred on July 25 in the Gates No. 1 mine of the H. C. Frick Coke Co., at Gates, Pa. The other members of this committee were Richard Maize, Silas S. Hall, W. H. Howarth and Harry Phythyon. Their report submitted to Joseph J. Walsh, Secretary of Mines, of Pennsylvania, gives two probable causes of the explosion and makes certain specific recommendations.

The Gates No. 1 mine is in a gaseous territory. The Pittsburgh seam, which at this mine is 8 ft. thick, is being worked. The location is on the east side of the Monongahela River about twenty-five miles south of Brownsville. A shaft 250 ft. deep forms the main entrance to the mine. Ventilation is provided by a force or blower fan driven by steam which produces a pressure of 2.5 in. water gage. The inspector's report here reproduced describes the details of the mine layout and the conditions as observed by the committee.

The air is forced down a compartment of the main shaft, the airway being separated from the hoisting shaft by a concrete partition. The air after leaving the shaft is conducted for some distance along airways parallel to the main haulage roads but later enters these roadways which thereafter serve as intake airways. The air is conducted through the workings and then returns to the surface at outlets provided for that purpose. It is prevented from making a short circuit to the hoisting compartment of the main shaft by a series of doors on each main haulage road leading to the main shaft.

## EXPLOSION CONFINED TO ONE SECTION

The mine is divided into three sections to one of which, the North section, which is adjacent to the Palmer mine of the same company, the explosion was confined. About 51,600 cu.ft. of air per minute enters through No. 6 Butt entry and a parallel aircourse and is distributed throughout the workings of the section. This entry forms the longer side of the triangle occupied by the area described. It is also the roadway through which all the coal in the section is brought to the shaft.

On one side are two parallel airways separated from the rest of the mine by a barrier pillar. These two parallel headings are the return airways for that side of the triangle, the other side of which is bounded by an old gob. Another pair of adjacent headings, which are parallel to No. 6 Butt and on the same side as the rooms turned off that roadway, serve as return airways for that side next to the old gob and nearest to the hoisting shaft.

Rooms have been turned off No. 6 Butt and as a rule they have been driven north on the face, until they reach a boundary of the triangle. The first rooms turned off No. 6 Butt are short but they increase in length successively until No. 15 room is reached.

Thereafter each in its turn is shorter than the one that precedes it, No. 24 room being the last room turned. No. 13 room is about 1,500 ft. long, extending from No. 6 Butt to the apex of the triangle.

The rooms are crossed at frequent intervals by crosscuts and entries so that the triangle resembles somewhat a part of a huge checkerboard except that it is crossed by several diagonal entries which have been disregarded as a part of the plan of mining the coal in the area being described.

At the head of each room the process of extracting the room pillars has been going on for several months so that a gob extends along two sides of the triangle making two gob lines which meet at an apex at No. 13 room. The accompanying map shows the layout of the triangle.

Two parallel entries with brick-and-cement stoppings connect this triangular section with the main return aircourse of the adjacent Palmer mine, which is ventilated by an exhaust fan with a water gage of about 3 in.

## SMOKE ISSUES FROM AIRSHAFT OF PALMER MINE

About 7:30 p.m. on July 25 smoke was discovered issuing from the airshaft of the Palmer mine, and it was supposed at first that the smoke was caused by a fire or by an explosion in that mine. Upon investigation it was discovered that the smoke was the outcome of an explosion in the Gates mine in the section adjacent to the Palmer mine. One of the 13-in. brick-and-cement stoppings which had been built in these entries to separate the two mines was torn down by the force of the explosion and thus the smoke noticed at the Palmer airshaft was carried in the air current from the Gates mine.

In addition to the broken stopping in the entry leading to the Palmer mine the inspectors found evidence of much violence extending over a large part of the section. There was not much evidence of heat nor violence noticed along No. 6 Butt entry nor in the first few rooms turned off No. 6 Butt, although a number of brick stoppings were demolished along that entry. The violence was considerable in the central part of the triangular area and toward the apex of the triangle opposite No. 6 Butt entry. The heat seemed to increase toward the western corner of the triangle as was evidenced by the fused coal dust that was plastered on posts and other surfaces.

The forces and flame traveled in different directions but seemed to radiate from the neighborhood of No. 21 room, where six dead bodies were found. Near the end of that room one narrow place driving westward toward the gob had recently been cut by an electric shortwall machine. Another similar place 25 ft. farther back from the head of the room was partly cut and evidently this cut was being made when the explosion occurred. On the roadway of the room, between the place that had just been cut and the place that was being cut, many tangled detonator wires were found, indicat-

ing that about one hundred electric detonators were assembled together there, the leather case in which the detonators were carried by the shotfirers being found empty and in good condition at the head of the room. Most of the detonators were found to be destroyed.

#### SHOTFIRER AND ASSISTANTS FOUND IN SAME ROOM

Close by the bundle of detonator wires a place was found where a quantity of permissible powder had been burned. Apparently it had lain on the ground in the space between two ties in the track. The room was timbered with legs and crossbars at this place, and these timbers were deeply charred. Three flame safety lamps were found extinguished at this point also, indicating that the shotfirer and his two assistants were together here when the explosion occurred. One of the safety lamps and three exploded detonators were found under a piece of slate that had fallen from

the roof. This safety lamp was found lying on its side with its glass broken, but the evidence indicated that the slate fell after the explosion had started. There was no evidence that any shots had yet been fired in the working places.

It appeared from all the evidence available that while the shotfirer and his assistants were at this point in No. 21 room arranging their detonators and powder for convenient use a flame approached from some source which exploded the detonators and burned the permissible powder, although it may be that the detonators themselves initiated the explosion.

In addition to these three men, a cutter and his helper and a timberman were found dead in this room. A driller and his helper were found at the head of No. 19 room. Another cutter and his helper were found near the head of No. 12 room.

An accumulation of gas might have taken place in

Map of the Northern Section of the Gates Mine of H. C. Frick Coke Co. Where an Explosion Occurred July 25, 1924

The explosion blew out a 13-in. brick-and-cement stopping in a heading leading through the large barrier pillar between the Palmer and the Gates mines. This will be seen marked B. S. and Dm (Brick Stop-

ping and Demolished) near the left side of the plan. The explosion seemed to center from the neighborhood of No. 21 room, where six dead bodies were found. On the roadway of the room were the tangled

wires of about one hundred detonators, mostly exploded. Close by a place was noted where a large quantity of powder had burned, charring the legs and crossbars by which the place was timbered.

Room 21 where the six men were found, due either to a sudden outburst of gas caused by a heavy fall or to a gradual issue coupled with a disarrangement of the ventilation, which accumulation could have become ignited by an electric arc, or possibly by the accidental firing of the detonators. This explanation seems the most reasonable to the inspectors, but the evidence was insufficient to make this opinion positive.

The section of the mine under consideration is known to generate some explosive gas, but the ventilation had been restored when the inspectors explored the scene of the explosion on Monday, and they found no gas except at one place. Here it was issuing from the floor. There had been no explosive gas noted on the mine report books for this section of the mine since Dec. 14, 1923.

The H. C. Frick Coke Co. has spared no pains nor expense to make and keep this mine in a safe condition. Sufficient air was supplied to give adequate ventilation. A system of sprinkling with pipe lines and hose had been provided so that all the working places might be sprinkled with water before the shots were fired. A man accompanies the shotfirer for this

purpose. The coal is sprinkled by the loaders as they load it. It is cut and shot on the night shift. Permissible powder only is used for shooting. Electric cap lamps are used exclusively except by the officials and shotfirers who use flame safety lamps but one such lamp is furnished to each cutter in addition to his electric cap lamp. But, considering the quantity and character of the work being performed in this section on the night shift, the supervision was insufficient.

The inspectors close their report with certain recommendations suggested by their investigation: 1. That the ventilation be arranged so as to reduce to a minimum the chances of short-circuiting the air current. 2. That proper examinations be made and efficient supervision be provided for the workings on the night shift. 3. That the Federal Bureau of Mines withhold its approval of electric detonators unless the type submitted for approval provides against their being exploded accidentally by electricity. 4. That greater care be exercised in the handling of detonators and explosives. 5. That all electric wires and equipment be installed, maintained and operated so as to reduce the danger of arcing to a minimum.

## Engineers Study Needs of Industrial Centers in Coal Storage Report

STORAGE will assure a continuous and reliable supply of coal throughout the country, it is asserted in an analysis of the needs of communities and industries accompanying a series of summaries of regional conditions to be embodied in the report of the Coal Storage Committee of the American Engineering Council, of which W. L. Abbott, of Chicago, is chairman. The complete report, Ex-Governor James Hartness, of Vermont, president of the Council, said in making the announcement, would exceed 100,000 words, and would be made public following a meeting of the administrative board of the Council to be held at the headquarters of the Western Society of Engineers in Chicago, Oct. 17 and 18.

"From the standpoint of consumers in both large and small communities," according to the analysis, "the first requisite is that the supply should be freed from irregularities having their origin largely in artificial causes. There is a negligible amount of intentional manipulation of the market, but flurries and near panics are frequent. Consumers often are responsible."

### ESTABLISH AVERAGE MONTHLY STANDARD

The Engineering Committee has established a storage practice in leading industrial centers, using as a standard an average monthly shipment plan. As to this the analysis said:

"Evidently it is essential that the consumer store coal. The ideal practice would be for him to store during the summer a large portion of the amount consumed during the winter. But such an ideal is too much to expect, hence the committee has set up as a standard an average monthly shipment plan.

"Compliance with such a standard would mean that the consumer would store a minimum amount of coal and such would not be in storage for a great length of time; the transportation agencies would be relieved of the inordinate peak demands and would be enabled to move coal at less expense than now; the producer, knowing what his monthly demands would be, could

so arrange his operation schedules as to produce coal at a much lower cost per ton.

"Eventually, should such a practice become generally and regularly followed, the amount of storage required would be materially reduced, but this cycle of improvement can be initiated only by consumers."

The Chicago committee of the Council's main committee, it was said in analyzing conditions in that city, based its conclusions on data from fourteen representative industries having a consumption of 4,640,000 tons, representing 15 per cent of the total coal moving into the Chicago district.

"Only 6.7 per cent of the annual consumption of these industries should be stored if all of the users were purchasing coal on the basis of uniform monthly shipments," this committee reported. "This is a larger percentage than that pertaining to Philadelphia, but in comparison with most of the medium to large cities of the country it is a very low percentage.

"It means that if users generally in this district were purchasing coal on a contract basis with equal monthly shipments, the aggregate storage bill would be but a small amount when distributed over the entire year's supply. Undoubtedly some industries would be obliged to store a larger percentage, but the typical establishment is in a fortunate condition in this respect."

The uniform monthly shipment plan recommended by the engineers for Chicago, would, it was said, result in monthly shipments of 386,550 tons to 14 consumers, seasonal storage of 295,500 tons, amounting to 6.4 per cent of annual consumption, reserve storage 7.1 per cent of annual consumption and total storage 13.5 per cent of an annual consumption of 4,638,600 tons.

**TAR YIELD OF WESTERN LIGNITES.**—A large number of assay retort tests of samples of lignite taken from public lands in the Western states have recently been made by the oil-shale laboratory of the Bureau of Mines, Boulder, Colo. The Colorado lignites so far tested yielded from 8 to 10 gal. of tar to the ton. Samples of Wyoming lignite yielded as high as 20 gal. to the ton.

## Why Not Use Approved Equipment in Place of Open or Half-Safe Type?

Electricity Causes Many Disasters and Fires—To Date None Has Been Caused by Flashes from Permissible Apparatus—Lists Large Variety of Equipment Bureau Has Approved

A DISCUSSION of safe electrical equipment for gaseous and dusty coal mines is given in publication No. 2,626 by L. C. Ilsley, electrical engineer, U. S. Bureau of Mines. This paper starts by comparing the buying of approved equipment following a disaster to "locking the stable door after the horse is stolen," then goes on to discuss some recent accidents and their effect.

"An open type of electric coal drill was used in a gaseous mine in West Virginia. This was the probable cause of the death of twenty-seven men. A half-safe type of electric coal-cutting machine was used in a gaseous mine in Pennsylvania. This was probably the cause of the death of thirty-six men. An unapproved, unsafe type of flame safety lamp was used in a gaseous and dusty mine in Utah. This was the alleged cause of the death of 171 men. All three disasters happened within the last six months, and it would seem would have been avoidable if proper equipment had been used.

"It is understood that more rigid requirements will be enforced in West Virginia. The committee of state mine inspectors made definite recommendation for improving the conditions in the Pennsylvania mine to which reference has been made. The Industrial Commission of Utah has already issued new orders which will prevent the use of unsafe lamps in that state.

"These acts and recommendations are all good and will help to prevent accidents in those states in the future. Is it not a pity that such recommendations and orders were not made a little earlier before the toll of life had been exacted? Is it not unfortunate that other states will not take these lessons to heart and safeguard their mines before and not after disasters take place?

"Electric current can cause accidents in five general ways as follows: (1) By shock to persons; (2) by igniting powder; (3) by igniting gas; (4) by igniting coal dust; and (5) by setting fire to flammable material such as timber and coal. Many accidents from these causes are preventable if proper care is taken. Most of the accidents caused by sparks and flashes from electrical apparatus would not take place if approved electrical equipment was used. By approved equipment is meant equipment that has been tested and formally approved by the Bureau of Mines. So far as known, up to the present time, no disasters have been caused by sparks or flashes from equipment having the Bureau's approval.

"The table accompanying this article and compiled by M. W. von Bernowitz from records of the Bureau of Mines covering the period 1910 to 1924, shows disasters and fires caused by electrical apparatus and circuits.

"The table shows that in the twenty-six accidents reported, 499 lives were lost and 86 other men were injured; besides there was much damage to property.

"During the past fourteen years the Bureau of Mines has, in co-operation with manufacturers of electrical machinery and equipment for mines, conducted thousands of tests on various machines and apparatus submitted by the manufacturers to determine whether the device is safe for use in explosive atmospheres. If the

machine, or any part of it, is not safe, the bureau and the manufacturer work together to eliminate the unsafe features. When the machine finally passes the bureau's test, it is formally approved for use in coal mines where hazards from gas and dust occur. Several classes of equip-

ment have been tested, and there is a steadily growing list of approved equipment recommended for use wherever such equipment is needed.

"The electrical equipment so far formally approved by the Bureau of Mines includes five storage-battery

## Coal and Coke in House-Heating Plants

Accurate data on the effectiveness of combustion of bituminous coal and coke for generating steam under hand-fired low-pressure cast-iron boilers of a type actually used in heating large buildings have been obtained as the results of a study at the Pittsburgh station of the Bureau of Mines. The experimental work has been under way since early in 1922. The effectiveness of different methods of firing the different coals tested was determined, as well as the relative value of the different fuels used. The results showed that the bituminous coals from the Pittsburgh and Lower Kittanning beds, of Pennsylvania, and the coke were of about equal steaming value at the lower pressures but at medium and higher pressures permissible with this equipment, the coke had about 90 per cent of the steaming value of the bituminous coal.

# Texas Lignite Field Sets Steam Shovel to Work

Stripping Methods May Eliminate Underground Mines in Parts of Texas for the Overburden Is Often Light

BY HOWARD MARSHALL  
Austin, Texas

Shovel of Western Securities Coal Co.

ONE of the most important events in the history of the Texas lignite industry is the opening and successful operation of the strip mine in the Rockdale lignite fields by the Western Securities Coal Co., a subsidiary of the McAlester Coal Co., of McAlester, Okla. The importance is due to the fact that by this new process, it has been estimated lignite coal can be mined for from one-half to two-thirds, or even less, as much as by the established mining methods now in general use throughout the state.

As the result of the ability of this new strip mine to produce coal so cheaply, prices on lignite coal have been slashed to unprecedented depths. The city of Austin, which is the biggest single user of lignite in the state, before the opening of the price war, paid \$1.50 per ton, f.o.b. at the mines; now it pays \$0.96 per ton.

In the Texas lignite mines, the coal is extracted from depths varying from 50 to 300 ft. by means of shafts, and by hand labor. The producing cost of lignite by this method is from 50 to 60 c. per ton; by the new stripping method, it is estimated to be not more than 40c. per ton. Reliable authorities declare that the Western Securities people can produce lignite at 20c. per ton as soon as the markets justify greater production.

In order to meet the competition, the majority of the lignite operators in the state have cut the pay of the diggers from 30c. per pit car of 1,600 lb. to 25c.

Until the coal had actually begun to leave the stripping few people believed that the venture of the Western

Securities company would be a success. They believed that this attempt to strip mine coal would result as did that of the Federal Fuel Co., which proved to be one of the most tragic stories of failure in the history of the Texas lignite industry.

The plan of the Federal Fuel Co., organized in 1918, differed from other types of stripping mainly in the kind of machinery which it proposed to use. Two giant devices, not steam shovels, strip-mined the coal and loaded the coal cars in the mine yards.

However, misfortunes followed closely on the heels of these adventurers in strip mining. The machinery broke, adverse weather conditions hampered the work, and just as it seemed that the project would succeed, the treasury of the company became exhausted, and the whole scheme had to be abandoned. The total loss sustained by the company officials totaled half a million dollars.

The Western Securities Co. came into the Rockdale lignite field about a year ago when it leased the property of the Federal Fuel Co. This property consisted of 1,938 acres, of which 748 acres were actually tested by the process of sinking small wells at various points. The bed is 14½ ft. thick, and most of it is overlaid with 20 ft. to 40 ft. of sandy clay, which is easily stripped.

According to claims advanced by the Federal Fuel Co., this field contains 20,000,000 tons of the finest lignite coal in the state. President Puterbaugh has

## Stripping 15-Ft. Seam

Overburden is about 25 ft. thick though it hardly seems so, judging by the thickness of the lignite. Note the cars on the lignite berm and the stripping shovel in the rear. This scene is on the property of the Western Securities Coal Co., near Rockdale, Texas. The use of shovels is lowering the cost of producing lignite considerably, wherever as here the lignite is thick and the cover merely enough to keep the bed in good condition.

#### Another View

This, taken from above, gives a good idea of the thickness of overburden. The loading shovel can be seen excavating the lignite in a cut 15 ft. lower than the big stripping shovel which is kept 50 yd. ahead of the loading equipment. The photograph was taken when the stripping shovel was still making its first or "box" cut.

been quoted as saying that there is enough lignite in this bed to supply all the industries of Texas for the next ten years, at the present rate of consumption.

The property is located about six miles from the main line of the International-Great Northern R.R., and approximately nine miles from Rockdale. The Western Securities has rebuilt an old spur from the main line to their mine at Sandow, and have incorporated it under the name of "The Rockdale, Sandow, and Southern."

Machinery of a value of more than two hundred thousand dollars has been moved in by this new company. This equipment includes: Two steam shovels, one standard locomotive, and a large number of tools for use in the machine shops of the company.

The strip which has been opened is at present perhaps a quarter of a mile long, 80 ft. wide, and 40 ft. deep. The overburden of the lignite here is at least 15 ft. The shovels can uncover and mine, in an eight-hour day, about 25 ft. of the lignite.

The large shovel rests on the bed of lignite which has been uncovered, and which has been swept smooth by two men working with steel brooms. It keeps about fifty yards in advance of the small, coal-removing shovel. The track, on which the coal cars are moved into the long strip down an incline, rests on the top of the bed of coal, just to the right, and above the small shovel. At the present time, these cars are moved by the short pushes of the big dipper of the small shovel, but it is said that the company will presently purchase another locomotive to do this work.

According to State Mine Inspector N. M. Bullock, of Rockdale, Tex., these cars can be loaded in 12 min-

utes. As the average coal car will hold about 40 tons of lignite coal, the shovels can uncover, at this rate about 1,200 tons of lignite coal in one day of eight hours. Allowing for unforeseen delays, each day should see 20 cars of coal leaving the strip. And by simply stringing lights across the cut, and by working three shifts of men, at least 2,400 tons of lignite coal can be mined in a 24-hour day.

Industrial chemists have recently analyzed samples of the coal from the strip at Sandow, and have declared that it contains practically the same number of heat units as that which comes from the deeper stratas of lignite. The lumpy condition of the coal will probably necessitate the use of crushers for use with furnaces which are mechanically stoked.

The rising prices of oil are inducing a number of power plants, which have heretofore used fuel oil in their furnaces, to introduce lignite. In other words, because of its two hundred thousand dollar investment, the Western Securities people do not wish to slash lignite prices further, as long as there is a reasonable market for their output. It is due to these factors, in the opinion of many mining men, that the small operators are still enabled to compete with the big strip at Sandow.

But with the coming of the dull months next winter, a hard season is foreseen for the shaft mine owners. There is little doubt that the strip can produce coal far more cheaply than they. And when the annual market depression comes to the lignite industry, the keener competition, it is believed, will close many of the small mines. Some mining authorities are of the opinion that other strip mines will be opened quickly in imitation of the example set by the Western Securities people. If this is done, Texas will witness the most radical change in mining methods that has occurred in the history of the industry.

Tippel and Power House, Consolidated Coal Co.

This mine near Rockdale is somewhat typical of the lignite mines of Texas. The surface structures are usually light and impermanent.

COAL-DUST EXPLOSION GALLERY IN INDIA.—Consequently on a severe explosion at Parbelia Colliery in the Ranganj coal field which killed seventy-four persons and was ascribed largely to coal dust, a committee was formed to study such dangers. The committee had had built a gallery 150 ft. long and from 3 to 4 ft. in diameter on a site near the headquarters of the Department of Mines at Dhanbad. The Parbelia Colliery is about 1,500 ft. deep. All the galleries are now being stone-dusted with shale ground to the necessary fineness in a ball mill.—David Penman, *The Mining Institute of Scotland*.

# Making Power Contracts That Will Save Your Purse

Power Schedules Should Be Selected with Care—Large Savings Often Can Be Made by Buying Under Two Schedules—Contract Must Be Based on Intimate Knowledge of Conditions at Mine to Be Supplied

BY W. H. RUSSELL  
Farmington, Ill.

**A**MONG the many ways the electrical man can effect economies at a coal mine, two are of prime importance, viz., efficient purchase or generation of power and elimination of unnecessary energy losses. The schedule under which power should be purchased is the subject of this article.

This is important because large sums often can be saved with no expense or trouble except the time necessary to make a study of the local conditions under which the power is used and of the different power schedules under which it may be bought.

In the purchase of central-station power large sums of money are often wasted by the selection of the wrong schedule or the use of but one when two different rates might better be selected. Most power companies have several different schedules available, and, though they are usually willing and anxious to help the consumer of their product to select the most advantageous rate, they are quite often unacquainted with the peculiarities of each coal-mine load and make incorrect recommendations. Likewise, the coal-mine executive is often unacquainted with the peculiarities of power rates and is sometimes resigned to the habit of regarding power bills as a necessary evil rather than a chance to make substantial savings with practically no expense.

## SLIDING SCALE GENERALLY USED

Though there are many different forms of power schedule, most of them are alike in that they consist of two parts, viz., a demand charge and an energy charge.

One schedule commonly known as the estimated demand rate is probably that most generally used; it consists of, first, a method of making a fixed annual or monthly demand charge and, second, a method of allotting, in proportion to the maximum demand, the total consumption of power to a sliding scale.

With this schedule, the maximum demand is based on the active load which is a certain percentage of the total of all motors or other power-consuming machinery connected to the system. This percentage generally takes into consideration the number of motors or other devices in use and other factors which might have a bearing on the probable maximum demand for power by the whole system.

At best, this is a haphazard method with much chance for unfairness to either party to the contract. There is always more or less trouble concerning changes in the connected load, especially when another locomotive is placed in service or one is taken out of service. A change should be made in the demand charge whenever the connected load is increased or decreased, but this is liable to happen so frequently that it will be neglected with loss to somebody.

In spite of the clumsiness of this method of determining the demand charge, it is quite generally used, and often the reason for its selection is that the low rate for the actual energy consumed is attractive.

When the mine works steadily at full capacity, the demand charge is not burdensome because it is counterbalanced by a large energy consumption which often results in a low average cost per kilowatt-hour; but if the mine has to be shut down or the tonnage reduced part of the year, the demand charge is often a heavy burden, particularly if nothing is running but a few pumps and the fan. Usually, on such occasions, the fan is run only a part of the time and then at reduced speed.

The second schedule is based upon a measured maximum demand and automatically takes care of any change in the connected load. The actual maximum demand figure used in computing the bill may be established monthly or yearly or for whatever period of time is fixed by the power company.

By this method the maximum demand is measured and recorded continuously on a chart driven by a clock, and the demand thus obtained is used in computing the bill by various methods. Generally the maximum demand is used to determine the quantities to be charged at the different rates, thus:

First 30-hr. use of max. demand .....	3,000 kw.-hr. at 10c. per kw.-hr.
Second 30-hr. use of max. demand .....	3,000 kw.-hr. at 7c. per kw.-hr.
All in excess of 60-hr. use of max. demand .....	44,000 kw.-hr. at 2c. per kw.-hr.

Various discounts are then allowed for prompt payment, limited-hour service, quantity used, power-factor correction, etc.

## WHAT CONSTITUTES MAXIMUM DEMAND?

Maximum demand is a term which is commonly misunderstood. The general understanding seems to be that it is the instantaneous maximum load. This interpretation, except in rare cases, is wrong. The maximum demand is the average load for a given time interval, usually 30, 15, or 5 min., or in the case of violently fluctuating loads an even shorter interval of time. Thus a motor with a steady load sufficient to cause it to use exactly 50 kw. would register a demand of 50 kw., regardless of the time interval. If the demand meter is fitted with a time-interval indicator of 30 min. and the load were reduced to nothing for the first half of the 30 min. and increased to 100 kw. the second half, the recorded maximum demand would still be 60 kw. during this particular 30-min. period.

The energy charge on these schedules is applied by a sliding-scale rate based on the power used, so that the higher the consumption the lower the average rate up to a certain point; after this point is reached, the charge is usually a low rate per kilowatt-hour for the entire quantity used. Some consumers of power think this a very expensive rate, but under certain conditions it has decided advantages; principally at mines where the output of coal is large for but a few months of the year. The rate per kilowatt-hour may be somewhat

high during operating periods, but the demand charge during the slack months may be eliminated, and the result is an advantage for the entire year.

When using the measured demand rate it is sometimes practical to reduce the total power bill by cutting down the maximum demand by reducing the tonnage, but in the case of the estimated demand rate any change in the load and demand charge usually means a conference with the power company and a complete change in the contract, which soon becomes burdensome, and is likely to be neglected.

In case of the complete suspension of mining operations the measured demand rate system is very convenient and at the same time economical because the pumping and ventilation load may be so regulated as to keep the demand down to a minimum. At the same time the occasional use of a hoist or locomotive will not increase the maximum demand, if other equipment is first shut down, whereas the estimated demand rate fixes a demand charge in proportion to the total of all the equipment which is connected and in running order. If the rule be strictly enforced this prohibits the occasional use of hoists and locomotives and also prevents any reduction of the demand charge during a suspension.

Some power companies permit the use of two separate rates. This is a benefit to many coal-mine consumers as invariably the class of load which is steady earns a much lower rate than one which is subject to violent fluctuations or which is on but a few hours of the day. Most coal mines which use electric power to any great extent have an abundance of both the steady and the intermittent loads and can take advantage of the two rates, if they are permitted to do so. The steady load, of course, consists principally of fan and pump motors. Fan motors consume an enormous quan-

Table I—Showing Cost of Power for Various Purposes

Type of Service	Energy Consumed in Kilowatt-Hours	Cost in Cents per Kw.-Hr.	Total Cost
Ventilation.....	72,910	1.68	\$1,229.34
Cutting and haulage.....	130,531	2.5	3,263.29
Pumps and misc. equipment.....	10,880	2.5	272.00
Total.....	214,321	Ave. 2.22	\$4,764.63

tity of power and usually constitute a 24-hr. a day load, which is extremely desirable to the power company and permits of a low rate. Mining machines, locomotives, hoists, etc., work only when coal is being hoisted and do not earn so low a rate as a fan.

It does not cost a power company much to have two separate metering equipments and where two schedules are available the average coal-mine consumer does well to take advantage of them.

Table I shows the quantity and the cost per kilowatt-hour of all the power purchased at a mine of 1,000 tons daily capacity in a 4-ft. seam during the year 1923, when there were many idle days. This power was purchased under two separate contracts and metered separately by the power company. The principal expense in connection with the additional metering equipment was for one extra meter and two current transformers at a total cost of less than \$100.

It will be noted that ventilation earned the lowest rate, using nearly 56 per cent as much power as used by cutting and main haulage equipment. As a check on results, the power bills are figured according to each rate every month and for the year 1923. The cost of the power, if it had all been purchased on one of the

schedules, would have been \$5,358.03, and had it all been purchased on the other rate, the cost would have been \$7,149.36. This scheme has been working for several years at two mines owned by the same company and has never failed to show a greater saving than that in 1923.

At another mine an additional discount of 15 and 5 per cent is allowed from the power bills because no power is used between 4 p.m. and 8 p.m. during the winter months. This offpeak service is not always permissible but, if available, it may be applied to service supplying power for mining machines, locomotives and hoists used only during the day.

The purchase of power must be treated as a specific problem for each mine and in order to arrive at the best solution one must be familiar with the power requirements and how they will be influenced by probable market conditions. The anticipated installation of additional machinery, as well as the technical side of power consumption and rates, also must be considered.

## Pays for Slate and Slack Removed

IN GREAT BRITAIN, as in the United States, the retailer of coal is under fire, Mr. Shinwell, the Secretary of Mines, charging that the prices are excessive. In a reply by the Coal Distributors' Information Department, 27 Southampton St., London, W. C. 2, entitled "The Price of Coal" (16 pp. paper bound), the whole question as to retailing costs is discussed and it is stated that the average net profit of six representative London coal merchants has been shown to Mr. Shinwell as approximately 18c. for each ton of coal over a period from 1921 to 1923. A practice, apparently general in Great Britain, is to screen the coal at the retailer's yard, the men being paid 36c. per ton for all small coal thus obtained, this payment being additional to the wage rates for the work of loading. Similarly the men are encouraged to pick out slate by a payment of \$2.42 (10 shillings) per ton of slate picked. "From these facts," says the booklet, "the desire and the effort of the merchants to send out the coal in satisfactory condition must be apparent; it is not a question of altruism, but of common sense, the satisfaction of customers being essential to continued custom."

## Will Try to Find Better Refractories

A co-operative agreement has been made between the Department of the Interior and C. A. Hirshfield, of Detroit, representing a group of large central power-plant operators, to make a survey of present conditions relating to the use of power-plant refractories. The survey will be conducted by engineers of the Bureau of Mines. With the present high ratings at which boiler plants are being operated and the increasing use of pulverized coal with its attending high temperatures, the refractories now available for lining boiler furnaces are proving inadequate. In this survey a study is being made of the characteristics of refractories now available for use in power-plant boiler furnaces, and the conditions under which they are used, their life in operating practice under the conditions prevailing at different plants and the way in which the refractories now marketed fail to meet these conditions. The purpose of the survey is to obtain fundamental data to be used in bettering refractory service.

# France—Its Present Attitude Toward Germany and Its Reconstruction Achievements

BY E. J. MEHREN

Vice-President, McGraw-Hill Co., Inc.,  
New York City

COMING to France after visiting Germany and noting there the transformation of spirit and the indications of reviving strength, one naturally asks whether the French, if aware of these developments in Germany, are formulating a policy that will work toward a peaceful solution of their differences. As everyone knows, the French policy to date, no matter how justified to the French mind as a means of forcing reparations or insuring security, has built up a hatred of the French in Germany. Such a feeling, taken in connection with the growing strength east of the Rhine, bodes no good for Europe.

Do the French realize what has happened in Germany? Do they foresee the possible results of the growing enmity? What policy are they formulating that will, peacefully, meet the situation? These are questions that force themselves on the visitor who, leaving Germany, comes to France.

The French do realize what has happened in Germany; they are watching Germany more closely than is any other nation. The result is what might be expected of men who do not blind themselves to the facts; a growing opinion that France must develop a harmonious relationship with Germany. The view is not yet very articulate, but Herriot's more conciliatory attitude, as contrasted with Poincaré's, is tangible evidence of the growing feeling. Force is seen to be ineffective; the invasion of the Ruhr is conceded to have been a blunder.

## COMMERCIAL TREATIES LOGICAL

The more friendly development, it is felt, should begin with commercial treaties, possibly commercial alliances. The German steel mills in the Ruhr, for example, can get their cheapest iron from Lorraine, now a part of France; Lorraine, on the other hand, needs German coal and can find the best market for its iron in the Ruhr. What more logical, then, than to come to agreement and to facilitate the co-working of these economically allied iron-mining, and coal- and steel-producing districts?

How much farther, if this step be accomplished, the relationship may and should go is hardly yet the issue. There is a feeling growing that a friendly relationship between the two nations must be worked out. Some—and they are of the school of Caillaux, the former premier, who was banished during the war because of pro-German activities—favor the formation of a Franco-German Alliance.

Of course, there are opponents, like Poincaré and his followers, of any plan

that looks with reasonableness upon relations with Germany. Poincaré however, has lost ground. The last election showed that the French want to try a new method of dealing with Germany; and the tide, judging by what could be learned here in Paris, is still setting away from Poincaré and toward the development of amicable relations.

Unquestionably, such a relationship between these countries would be the

Row of Miners' Houses near Lens

The "cities" around Lens, for which British and Germans fought so bitterly and which the Germans demolished so completely, are rebuilt, with the solidity, permanence and grace characteristic of the continent of Europe.

best assurance of peace in Europe. This the French are beginning to admit. It is a hopeful sign.

## FRANCE WANTS SECURITY

Repeatedly, in discussing these matters, it was impressed upon the visitor that France has no commercial jealousy of Germany, and that her sole desire is for security against German aggression. The reparations difficulty would long since have been adjusted had security been assured. This desire accounts, in part, for the Ruhr occupation, though the invasion was defended as a means of securing reparations payments. The Ruhr is the great steel center, the Pittsburgh, of Germany. In control of this district, France could prevent material preparations for war. It seems likely, however, that she will soon retire from the Ruhr (The London pact was concluded after this was written) and the question of security will be left to later conference, possibly under the auspices of the League of Nations.

But security she does want and until she gets it, through agreement with other nations or German alliance, it will be the controlling motive of French policy.

## RECONSTRUCTION ACHIEVEMENT

Admiration was recently expressed in these letters over developments in Germany. But no less should be the admiration of the French; they have done a mighty work in rebuilding the devastated regions.

Four years ago I stood in Lens, on the site of the Hotel de Ville (the city

hall), and surveyed in every direction the worst destruction I had seen in France. It was a city beaten flat, the streets obliterated, with no vestige of the pit heads that had once marked this, the richest of France's coal mining districts.

This week I stood on the same spot. Round about was an entire new city, housing as many people as before the war. There were gaps here and there, where new buildings had not replaced the old; there is work under way in almost every street, on pavements, or sidewalks, or services; there are large buildings still under construction, new churches, and two banks; but for practical purposes it is a complete town, a town resurrected and at work—resurrected and at work where only desolation had reigned four years ago.

Striking as is the impression within the city of Lens itself, the impression is even stronger when one motors to the heights of Notre Dame de Lorette (where 100,000 French soldiers gave their lives during the war) and looks down upon the whole area. The landscape as far as one can see is dotted close with new red-roofed towns, each surrounding the shaft of a single large mine. The impression would draw admiration from the dullest—admiration of the energy, the determination, the courage, the perseverance of the people of France.

Of course, the scars of war are still visible. Remains of trenches are found in Lens and in the country round about, while from the tangle of No. 11 shaft one can trace the wide swath of waste land—No Man's Land—where ran the main trench line, established when the English took Loos in the terrific fighting of September, 1915. Part of this trench line will be allowed to remain forever as a permanent memorial of the war.

## MINE RECONSTRUCTION

Much remains, too, to be done in the way of completing the reconstruction. Sidewalks are missing in large part. Many streets are unpaved or only temporarily paved. The churches and the municipal buildings are in hand only now or not yet started, the first efforts being put upon the recovery of the mines and upon housing. Probably two years more will be needed, in the Lens district, to finish the work.

To reinforce the general observations about progress, a few statistics will be given. The company operating the Lens concession (16 mines) will be taken, as an example. The Lens company before the war employed 12,300 men underground and mined 370,000

### Business Section in Lens

A few scaffolds attest that something yet remains to be performed, but Lens bears little sign today of the destructive hand of the invader. Reconstruction has gone on apace despite the delay in the payment of reparations.

metric tons of coal per month. On May 1 of this year, 10,458 men were at work underground, and the monthly tonnage was 175,000 (working conditions are still quite unsatisfactory). Of the 8,300 houses for workmen, 7,490 have been rebuilt and the population of the mine towns (32,250 in 1913) is now 30,284. Thirteen out of the 23 destroyed working shafts have been repaired, the headworks completed and put in service, and so have eight out of the 12 ventilating shafts. Of 35 million cubic meters of flooding water 31 million had been removed.

For French coal mines as a whole, the reconstruction figures show even greater progress than that of the Lens company. Of 200 mines destroyed, 145 are again producing coal, some of them, however, with temporary installations.

In the rebuilding of the tipples, electric substations, washhouses for the workers and the other necessary structures the best construction and the latest equipment have been employed, so that the Lens area has the unique distinction of a whole district modernly equipped. The plant layouts are impressive for their substantial character and the entire absence of the timber structures and shabby buildings so characteristic of our mines. All the buildings are of brick, both the mine structures and the homes for the workers.

### GENERAL RECONSTRUCTION

This picture of reconstruction is matched in every part of the destroyed area; in many districts, of course, there were no industries, so that this side of the Lens development is missing. For the whole of the destroyed region the figures stand as shown in the accompanying table.

Progress of Work of Reconstruction in Devastated Regions		
	Total Work to Be Done	Finished Jan. 1, 1924
Houses and farm buildings .....	741,900	605,900
Farm land to be reclaimed, hectares..	1,923,000	1,788,000
Factories to be rebuilt .....	22,900	20,872
New roads, kilometers	58,697	42,360
Railroad and other engineering structures .....	6,125	4,800

Finally, the population of these areas, which before the war had been 4,690,000 and which had declined to 2,075,000 at the time of the Armistice, has now risen (figures of Jan. 1, 1924) to 4,253,000.

One other comment needs to be made that the appreciation of the French accomplishment may be complete: France has, herself, raised practically all the money required for this reconstruction. Her reparation receipts from Germany have covered only a relatively small part of the cost.

This is a great accomplishment and one that explains the French insistence upon reparation payments. She was the chief sufferer and if her budget is now unbalanced it is because of her reconstruction charges. No wonder, then, that Poincaré had a strong following in his pressure on Germany. Would not any people who had placed upon themselves this very heavy burden tend to view the matter as they did. Let it be remembered, too, that in the wrecking of these regions France lost heavily of her income, for while the destroyed area was only one-fourteenth

### Garden Village at Lens

The permanent but box-line houses of this coal-mine town have the elaborate fences so common in French mine villages. The road is carefully made. In too many of our towns the feet of horses and pedestrians tread out the pathway and roadway.

### Compares Output Records In Kanawha Field

An interesting comparative statement of productive performance, showing the average yearly output in tons

per man during 1923 in connection with the operation of several mines in the Kanawha field of West Virginia has been prepared by A. O. Wilson, statistician of the Kanawha Operators Association, as follows:

### Comparative Statement of Average Yearly Output per Man in 1923 in the Kanawha Field

	Loaders	Cutters	Pick Miners	Inside Daymen	Outside Daymen	All Men
Co. A.....	2,030.0	29,523.0	1,995.7	2,924.9	6,764.4	981.1
Co. B.....	1,628.1	25,537.7	.....	3,120.6	5,559.2	828.8
Co. C.....	1,272.2	8,447.1	.....	1,270.4	3,274.3	488.6
Co. D.....	1,814.1	16,501.8	.....	2,492.4	4,730.2	806.1
Co. E.....	1,967.6	26,847.3	.....	3,522.6	8,678.8	1,048.9
Co. F.....	2,055.2	21,356.4	.....	5,424.7	6,663.2	1,144.0
Co. G.....	1,745.2	17,187.7	1,370.5	7,031.6	5,105.3	896.8
Co. H.....	1,417.1	14,742.4	.....	4,429.8	5,730.3	1,016.6
Co. I.....	2,298.2	23,509.8	.....	6,197.8	9,773.9	1,287.2
Co. J.....	796.2	13,495.1	.....	3,729.4	3,112.9	818.4
Co. K.....	2,125.3	22,017.4	.....	3,964.5	10,610.0	1,106.0
Co. L.....	1,792.7	21,302.1	2,189.6	4,518.0	7,168.3	1,075.0
Co. M.....	1,641.9	12,160.1	1,956.9	3,313.5	3,096.2	688.4
Co. N.....	1,970.9	19,981.6	.....	3,744.4	4,484.4	889.3
Co. O.....	1,142.7	14,271.1	.....	5,176.2	5,577.8	663.9
Co. P.....	1,222.6	24,548.0	.....	3,133.0	4,428.7	917.4
Average for fifty-two mines...	1,910.1	21,659.6	1,325.6	3,915.9	6,609.4	1,003.7

In the above statement *italic numbers* are below the average, and only one company registers "Clear."

## Resistance of Mine Headings To the Flow of Air

In Smooth Roadway Coefficient Only 0.000,000,003,6—  
Rough Floor Will Add 10 Per Cent—Cutting  
Out Crosscuts Reduced Friction 6 Per Cent

By J. W. PAUL, G. E. MCELROY and H. P. GREENWALD\*

IN 1922, the Bureau of Mines commenced an extensive research on coal-mine ventilation factors, large-scale tests being conducted in its experimental mine near Bruceton, Pa., over a period of two years. No. 2 butt entry in the experimental mine was selected as the section in which the tests were to be made. The entry had been driven by miners working under the union scale, the coal being undercut with a puncher machine and shot in the usual way. The butt entries are not driven parallel to the coal faces but at an angle of 10 deg. to the right, and the coal breaks along the faces and butts giving a kind of saw-tooth contour to the rib. There were recesses at intervals for the 8 x 8 in. posts used in the coal-dust explosion tests, and there were also instrument stations every 200 ft. which had a concrete front wall about 10 ft. long flush with the coal rib.

The roof was not timbered and was about as rough as the roof would be in any similar mine entry which had not had heavy falls. The usual mine track lay on the floor, the gage being 42 in. At the beginning of the tests the floor was fairly clear of loose spilled material but later became rougher. The entry was fairly straight, the greatest deviation of actual center line from survey center line being about 2 ft. There were cut-throughs to No. 1 Butt every 100 ft. which had airtight stoppings in them. This left dead ends about 20 ft. long opening out at intervals of 100 ft.

### UNUSUAL CARE TAKEN TO GET TRUE RESULTS

The test section was 335 ft. long and the two ends were trimmed so that they had the same cross-sectional area. The test method consisted of measuring the loss in static pressure between the two ends of the section simultaneous with the measuring by pitot tube of the volume of air flowing through the section. An air measurement station was constructed in No. 1 butt, all the air having to pass it and all the instruments were placed there. The development and trial of instruments and test methods took up much of the time and was responsible for many delays and repetitions. The results obtained and reported here are probably accurate within 2 per cent and are thoroughly reliable.

The coefficient of friction or friction factor for the section was computed from the formula:

$$k = Cd = \frac{5.2 AH}{SV^2}$$

where

- A = Cross-section area in square feet.
- H = Loss of pressure in inches of water.
- S = Rubbing surface in square feet.
- V = Average velocity of air in feet per minute.
- d = Weight of air.
- C = True co-efficient of friction.
- k = Co-efficient of friction as ordinarily used.

The value  $k$  involves the weight of air while  $C$  does not. The cross-sectional area was taken as the average of measurements made every 5 ft. and the rubbing surface was taken as the product of the length of the

section and the average perimeter determined in the same manner as the area.

The friction factor or coefficient of friction,  $k$ , was determined for this entry and was found to be 0.000,000,003,6 with air weighing 0.075 lb. per cubic foot. It was also evident that variations in the roughness of the entry would cause more difference in the value of  $k$  than variations in the weight of air which are normally met with except possibly in very deep mines or at high elevations.

The value just given was for an entry with reasonably smooth floor and may be taken as a minimum value for ordinary conditions. A moderate increase in the roughness of the floor increased the value of  $k$  5 per cent, and in an entry with much spilled coal or roof dribblings on the floor a 10-per cent increase may be assumed which would make  $k = 0.000,000,004$ .

It was also determined that a change in the velocity of the air caused a change in the value of the friction factor. As the velocity increases the value of  $k$  decreases but tends to become constant. The value given above is a fair average for velocities higher than 300 ft. per minute but as the velocity falls below 300 ft. per minute the value of  $k$  increases very rapidly. Thus at 150 ft. per minute the increase is 23 per cent and at 100 ft. per minute is 50 per cent of the value given for velocities above 300 ft. per minute. Thus at 100 ft. per minute the value of  $k$  would be between 0.000,000,005,4 and 0.000,000,006, depending on roughness.

### ALLOW 10 PER CENT FOR A CROOKED ENTRY

The effect of crookedness of the entry could not be investigated and the values given are for fairly straight entry. If the entry were so crooked that the survey center line would in some places be close to the rib, it appears probable that an increase in  $k$  up to 10 per cent would have to be allowed. On the whole a maximum value of  $k = 0.000,000,004,5$  appears to be reasonable for rough crooked entry with velocities above 300 ft. per minute.

Tests were made to determine the power consumed by eddy currents rotating in the cut-through dead ends. Board deflector brattices were placed across them flush with the rib of the entry and the resistance redetermined. Placing these brattices reduced the resistance of the entry about 6 per cent, the cut-throughs being located every 100 ft. Theoretically it takes less power to move the air in an entry if the cut-through dead ends are closed, but the money saving is so small that no special construction is justified. If there is much waste material to dispose of in driving the entry and a very high velocity air current will travel through it when finished, it may be worth while to gob the cut-throughs shut and plaster the front wall, but the erection of special deflectors cannot be justified.

The Pennsylvania bituminous mining law requires shelter holes at 15-yard intervals on entries having mechanical haulage. This condition could not be duplicated exactly in the experimental mine without the expenditure of much time and labor, but shelter holes were cut half-way between the cut-throughs making the distance between openings  $16\frac{2}{3}$  yards. The addition of these intermediate shelter holes did not cause any marked increase in the resistance of the entry. The shelter hole is only  $2\frac{1}{2}$  ft. deep and 4 ft. wide as compared with a cut-through dead end 20 ft. deep and 9 ft. wide. The power consumed by eddy currents in the smaller recess is negligible.

\*Chief of coal-mining investigations, mining engineer and assistant physicist, respectively, U. S. Bureau of Mines.

## News Of the Industry

### Explosion at Mine of Kemmerer Coal Co., Sublet, Wyo., Kills Thirty-Nine

On an "idle" day, between 11 and 12 a.m., Sept. 16, the Sublet or No. 5 mine of the Kemmerer Coal Co., located seven miles north of Kemmerer, Wyo., blew up, killing thirty-nine men out of the fifty-one who were working in the mine. Had the plant been actually in full operation about two hundred men would have been at work and possibly killed. The explosion is declared to have been severe. However, twelve men came out alive, emerging from the wreckage at about 5:30 p.m. The rest perished, the bodies being badly burned. On Sept. 23 the bodies of ten men had not yet been found, the quest having been blocked by falls.

The twelve men that escaped probably were saved from suffocation by the blocking of the airways due to caving. Part of the force was in a man trip going out of the main slope when the explosion occurred. Most of the bodies of these men were still in the cars when the rescuers reached the spot.

#### Mine Entrance Caved In

The explosion took place during a heavy rainstorm. It caved in the entrance of the mine and caused so much damage at that point that no rescue crews entered till 1:30 p.m. Apparently the damage in the mine was severe, as the removal of the bodies was accomplished slowly.

The force of the blast completely wrecked a long housing over the portal of the mine, which is a slope.

P. J. Quealy, the aged head of the company, was early on the scene and directed the rescue operations. Rescue-men were brought in from Rock Springs and Hanna. Sublet No. 5 has not had an explosion since 1881, but the Frontier Mine of the company blew up Aug. 4, 1923, killing 78 out of 94 men in the mine at the time.

The mine, strange to say, is quite wet, water being pumped from it regularly. It lies in the Cumberland basin, the seam dipping about 20 deg. and more steeply than the inclosing hills. It appears that much of the water that forms in the valley finds its way into the mines, perfect floods appearing at times when the static pressure with increasing depth causes a rupture in the reservoirs which the Cretaceous measures contain.

Some years ago the coal was being worked where it outcropped on the hills. The coal was dropped from this point down almost to the railroad level.

After a while, when the workings had extended far down the dip, it appeared ridiculous to be hoisting coal up such a height only to lower it again to about the same level. The bed being buried at tippie level a rock entry was driven to intersect it and thus cut off the unnecessary travel. At that time the company was operating a slow-speed fan but after the rock tunnel was driven a high-speed fan was installed.

In order to protect the miners, as the mine made gas, though not in large quantities, electric cap lamps were used exclusively. Spray lines were run within a short distance of all working faces. A hose extended these pipes to the loading point. Some men—perhaps two—were deputed to spend their whole time sprinkling the mine. Permissible explosives were used exclusively. The company had a good safety organization and had oxygen breathing apparatus.

The coal is a high quality bituminous with about 35 per cent volatile matter.

It appears that the source of the explosion was No. 12 entry but its actual cause is not yet known. The company believes it must have been personal carelessness, for the ventilation was excellent and all safety precautions had been taken. It will be remembered that the explosion at the Frontier mine was due to a fireboss opening a lamp to re-light it in a place where gas was present.

#### 46-Days' Coal in Storage, Say Purchasing Agents

The Fuel Committee of the National Association of Purchasing Agents estimates stocks of anthracite and bituminous coal in the hands of commercial consumers on Sept. 1 at 51,325,000 net tons. This is a decrease of 12,178,000 net tons when compared with the stocks on hand on May 1.

The report states that business as a whole shows an increase of 11 per cent for the month of August as compared with July and that the indications are for a continued slow but steady gain. It is estimated that industrial consumers had in their bins on Sept. 1 sufficient coal to meet requirements for 46 days. Consumers are advised that it would be well to place coal in storage now, coal prices remaining about the same as last month.

#### \$27,940,000 in Equipment For N. Y. Central Lines

New York Central, the Michigan Central and the Cleveland, Cincinnati, Chicago & St. Louis railroads on Sept. 16 asked authority from the Interstate Commerce Commission to issue \$20,955,000 of 4½ per cent equipment trust certificates. The proceeds would be used to purchase 4,100 coal cars, 3,200 box cars and other equipment, the total cost of which would be \$27,940,000.

#### West Kentucky Mine Signs Up At Union Scale

The coal mining interests of western Kentucky say they cannot understand what actuated the Phoenix Coal Corporation, at Drakesboro, Ky., in breaking away from the operators and signing the Jacksonville agreement with District 23, United Mine Workers. This was the first mine to accept the agreement—and the only one thus far. The plant is a large one, employing about 250 men. It is a comparatively new mining plant, having been established about seven years ago.

It is difficult to see how the union can figure that it has won a victory, in view of the fact that the mine probably can operate only on a temporary basis, under the 1919 wage scale with screenings at 90c.@\$1.10, and prepared at \$2.25@\$2.75, with some coal quoted as high as \$3. The company evidently is gambling on a stiff increase in the market in spite of the facts that the field is full of big stripping plants and non-union mines, which can produce far more coal than the normal production of the district and at far under the union production cost.

#### Five Miners Entombed by Explosion at Utah Mine

An explosion at the Rains Mine of the Carbon Fuel Co., near Castlegate, Utah, at 6 p.m., Sept. 21, entombed five miners. Rescue crews were working frantically the next morning to reach the imprisoned men. The mine did not take fire, as reported in earlier dispatches, and progress was being made in clearing away debris.

Mine company officials said that while a check showed only five men were at work cutting and blasting when the explosion occurred, it is possible there were others. Normally the mine employs about 200 men, but the work crews were off shift at the time.

Officials Confer on Status  
Of Trade Associations

Efforts to bring about a clearer definition of the legality of trade-association activities were initiated at a series of conferences held in Washington Sept. 22 by a special committee of the Chamber of Commerce of the United States with the Federal Trade Commission, Secretary Hoover and Attorney General Stone.

The committee, headed by Richard F. Grant, president of the National Chamber, laid before the government officials the results of a recent referendum reflecting the overwhelming opinion of business organizations that trade organizations perform a valuable public service and should be maintained. Arguments in support of this position were submitted, and the basis laid for a further conference to be held next month, when some statement of the government's attitude may be made.

The members of the committee accompanying Mr. Grant were Milton E. Marcuse, president of the Bedford Pulp & Paper Co., Richmond; George Publee, Washington; Alfred Reeves, general manager of the National Automobile Chamber of Commerce, and Elliot H. Goodwin, resident vice-president of the U. S. Chamber of Commerce.

Mr. Grant said after the conferences: "We are so much concerned over the question whether present trade associations fall within the scope of existing laws as in having a clear understanding of the proper function of trade-association activities. The special committee of the National Chamber formulated a series of resolutions with that in mind, and the overwhelming vote of the business of the country was in favor of its recommendations. We have made a careful search of the bills filed and decrees entered by the courts in cases relating to trade-association activities, and it is our belief that the activities proposed in these resolutions are entirely within the law.

"Apprehension has arisen among trade associations, of which more than 300 are members of the Chamber of Commerce of the United States, that all associational activities come under the ban, and some are afraid that mere membership might be the occasion for prosecution."

Know Any Bright Mules?

The most intelligent mine mule that Dwight Wilcox, superintendent for the Superior Coal Co., Gillespie, Ill., ever heard of was one which a driver in his own employ showed him. The driver was doing the gathering for seven working places and the mule had made just one round of the seven places when Wilcox came along.

"Betcha that mule can make the next round by itself," challenged the driver.

"Don't be so funny," scoffed the superintendent.

But the mule did the trick, delivering its seven empties and picking up its seven loads without a word or a touch from the driver, who merely followed along and hooked and unhooked the chain. So Wilcox was convinced.

And now who knows a more intelligent mine mule?

May Reduce Rates from Illinois  
To Anderson, Ind.

Rates for shipping coal from Illinois mines to Anderson, Ind., alleged to be exorbitantly high, may be reduced as the result of a hearing by E. L. Gaddess, of Washington, an examiner for the Interstate Commerce Commission. The case at issue was that in which the city lighting plant asked a refund of \$249 from the Big Four and Illinois Central railroads for alleged unfair rates charged for shipping coal to Anderson from Marissa, Ill. F. D. Roberts presented the case in behalf of the city. The City of Anderson alleges that the unfair rate cost \$246 on five carloads of coal, and in the petition the Interstate Commerce Commission is asked to allot the city that refund. Representatives of the railroad companies were in the city. A decision is expected in a few months.

Mr. Roberts says that the Interstate Commerce Commission will make a ruling soon in the case involving rates for West Virginia coal, in which it is alleged that Indianapolis gets a 35c. lower rate per ton than Anderson.

New Colonial Colliery Co.  
Absorbs Madeira, Natalie  
And Greenough Operations

Special to Coal Age

Scranton, Pa., Sept. 23.—With independent anthracite companies it is now practically a case of one merger after another. Following the announcement of the consolidation of the Temple Coal Co. and the East Bear Ridge company into the new Temple Anthracite Coal Co. came word of a practical completion of a merger of the Von Storch Collieries Co., the Legitts Creek Colliery and the West Ridge colliery by a group headed by former Governor William C. Sproul.

Now a third merger of anthracite companies has been completed. In the latest consolidation Madeira, Hill & Co. has taken over and merged the Madeira colliery and property in Plains, (Luzerne County), Pa., the Natalie colliery and property, the Greenough colliery and property, and 209 acres of coal lands located between them, known as the Hickory Swamp basin, all near Mt. Carmel, Northumberland County, Pa.

It is estimated that the combined output of all these operations will be 750,000 tons of coal a year. R. V. Norris & Son, of Wilkes-Barre, well-known mining engineers, have completed an exhaustive survey of all properties involved and report that the lands contain over 30,000,000 tons of coal available for market.

The new consolidation is known as the Colonial Colliery Co. and is incorporated under the laws of Pennsylvania. The main offices of the company will be in Philadelphia.

It is expected that the new company, under new management, and with a new breaker to prepare coal from the workings served by the Greenough and Natalie mines and also the coal from the tract of land lying between them will greatly exceed the earning power of the collieries operating separately. The new breaker will be called the Colonial colliery breaker and will be constructed of steel and concrete. It will have a daily capacity of 2,500 tons. The total cost of the new breaker, plant and development will be over \$1,300,000, it is stated.

Output and Value of Coal from Colorado Mines in 1923

(Compiled by U. S. Geological Survey)										
County	Loaded at mines for shipment (net tons)	Sold to local trade and used by employees (net tons)	Used at mines for steam and heat (net tons)	Made into coke at mines (net tons)	Total quantity (net tons)	Total value	Average value per ton	Number of Miners, a	Number of employees, All others	Average number of days worked

a Includes also loaders and shotfirers.

## Colorado Producers See Good Prospects for Fall

Colorado coal operators are discouraged. The consensus among them after the poorest summer on record, was that immediately after September a real pick-up in business is coming and that the winter is going to see a heavy and reasonably profitable movement of Colorado coal in all the markets it normally reaches.

Buying has been abnormally slow all summer for three main reasons, they say. The farmers in the Colorado coal market territory, comprising the states of Colorado, Nebraska, Kansas, Oklahoma and Texas, have been in a state of financial collapse. There has been further a feeling that prices were going to remain low. A third cause of delayed buying has been a desire to wait till the Interstate Commerce Commission reports a reduction in the Missouri River rates. The sudden realization that wheat in all those states is a bumper crop and is moving at a good price, and the cheerful indications of an oncoming bumper crop of corn have pretty well relieved the farmer of his pauperism. The days of violent price cutting appears to be definitely over, for price cuts during the summer brought no business at all. It is definitely known that another increase following the 25c. boost in August will be made in September. And there is no indication that the I. C. C. is going to announce its decision in the Missouri River case until late fall or winter.

### May Fix Rates on Mileage Basis

The feeling is general in Colorado that the country is going to get a shock when the commission hands down its Missouri River decision. It will not surprise Colorado to see the commission wipe out the present rate-making basis and adopt straight mileage as the basis for all coal rates. This was stoutly advocated before the commission by Harry F. Nash, of the Oakdale and Alamo coal companies, at the time of the hearings more than a year ago, and since then some others have come to share his feelings in the justice of such a basis. If the commission does adopt it, the rate structure covering a wide section of the United States would have to be adjusted to conform.

Western railroads never have been in better shape to handle traffic, even the Moffat road, hauling Routt County's 800,000 tons of coal, claiming to have remedied some of the physical defects which too often have made it impotent just at the times when coal needs to

## Coal Company Sells Fruit As Side Line

The unusual spectacle of fruit being retailed in a coal office can be seen in St. John, N. B. J. S. Gibbon & Co., dealers in hard and soft coal and former operators of a pit in the Grand Lake bituminous mining region, have entered the new business on a wide scale. The store formerly devoted to receiving coal orders and displays of different types and grades of hard and soft coal now is partly filled with domestic and imported fruit of all kinds. Outside the store, boxes of fruit are on display, with the prices attached. What started this firm in the new line was the purchase by J. S. Gibbon, senior member of the firm, of an orange and grapefruit grove in Florida. After disposing of the fruit from his own property, Mr. Gibbon started selling fruit in general in his coal office. J. S. Gibbon & Co. have been in the coal business in St. John for more than twenty years. During the slack coal season of the summer period, the fruit side line proved effective.

move. It is cited by an operator that Colorado's running time during the coal year 1923-4 averaged higher than that of several other Western states, partly because there has been less recent overdevelopment in Colorado. One important mine, Alamo, near Walsenburg, has been opened during the year but that is all. However, there are now two more new mines in immediate prospect. This indicates the confidence that certain Colorado operators have in the immediate future.

Oil is growing as a coal competitor, especially because of the recent strike in Routt and Moffat Counties. At present, however, oil has little if any advantage in price. This relationship probably will continue unless the Routt County oil dome turns out to be a tremendous producer. More than one coal company with retail branches is seriously considering the advisability of selling both oil and coal, so that if customers insist upon oil the coal man will not be a dead loser by it.

Coal has not been dealt any death blow in Colorado as is evidenced by the fact that the salesmen when hard after the machinery and equipment business during the past spring and summer found ready returns for their labors.

## Wilton Lignite Mine Reopens On Non-Union Basis

The Washburn Lignite Coal Co. has reopened its mine at Wilton, N. D., on a non-union basis, after having operated for the past six years under the union scale of the United Mine Workers. The mine was practically the only lignite mine operating on union basis the past year.

When the old union contract expired on March 31, the operators of the Wilton mine shut down their plant for the summer and did not sign the new contract.

The company stated that it could not meet the competition of a large number of mines which sprang up in the last two years, operating on a non-union basis at much lower wages than the union scale. The Washburn company offered a scale conforming to the wages now being paid by many of the bituminous mines in the East.

The proposed scale ranges from \$4.50 to \$5.50 per day for most company men, according to the company statement, with a separate scale for miners operating on a tonnage basis.

The union voted against the men returning to work on a non-union basis.

It is asserted by the company heads that many outside men are willing to go to work at the present wages, but that outside men will not be hired until the old employees have definitely settled their course.

The new scale of wages is as follows:

Pillar coal, per ton.....	\$3.85
Entry coal, per ton.....	.73
Room coal, per ton.....	.62
Cutting, per ton.....	.11
Slack, per car.....	.50
(NOTE—wage earned on per ton basis would range from \$7 to \$10 per day.)	
Drivers, per ton.....	\$0.04
or per day.....	5.00
Cagers, per day.....	5.50
Bottomshaft, per day.....	5.00
Motor men, per day.....	5.50
Trip riders, per day.....	5.00
Trappers, per day.....	3.50
Screen man, per day.....	5.00
Box-car loader men, per day.....	5.00
Other top men, per day.....	4.50
Head track man, per day.....	5.50
Track men helpers, per day.....	5.00
Head timber man, per day.....	5.50
Timber men helpers, per day.....	5.00
Pipe man, per day.....	5.50
Pumpers, per day.....	5.00
Head blacksmith, per day.....	5.00
Blacksmith helpers, per day.....	4.50
Carpenters, per day.....	5.00
Hoist engineer, per month.....	135.00
Barn boss, per month.....	125.00
Power-house engineers and firemen, per day.....	4.50
Boiler washer, per day.....	5.00
Section men, per day.....	3.50

## L. & N. Handles 8 per Cent Of Country's Coal Tonnage

The Louisville & Nashville R.R., in a recent statement, reported that in 1923 a total of over a half million cars of coal, or 8 per cent of the soft coal mined in the United States, was transported over its lines. The road with 5,038 miles of track, as compared with 251,175 miles of track in the United States, has 2 per cent of the total trackage, as against 8 per cent of the total coal tonnage, and demonstrates the importance of the road as a coal carrier. The tonnage handled comes from mines in Tennessee, Kentucky, Virginia, Alabama and Illinois.

### Recreation Hall For Miners and Their Families

In the mining town of Hanna, Wyo., belonging to the Union Pacific Coal Co. Hanna is devoted entirely to the mining of coal.

## British Marketing Methods Preserve Stable Relations Throughout Trade

Respect for Contract Obligations Marks Dealings of Producers, Middlemen and Consumers—Coal Exchanges Play Important Part—Advantage of Such Institutions Here Debated

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Because the British have been conspicuously successful in the marketing of coal, it was this aspect of the British industry to which the American coal men attending the World Power Conference, at London, paid most attention in their tours and studies, which the British facilitated in every way. Napoleon referred to Great Britain as a nation of shopkeepers. If "shopkeepers" be changed to "merchants" the British are glad to have the thought kept alive.

Marketing is the least explored field of our industry. For that reason the American observers regarded a study of British methods well worth while. They were much impressed with the stability of the relationships between producers, middlemen and consumers. The obligations of contracts are held in the highest respect. There is no complaint there that a coal contract means nothing.

The British contracts always contain a strike clause, but there is no provision as to free coal. Since car shortages are practically unknown in Great Britain, this prolific source of trouble in this country is not present there. A British mine can count on producing its normal output so long as there is no strike. In cases where the shipper is unable to supply the quota in one month, definite provision is made for releasing him from the obligation or for making up the deficit in a specified manner. The higher standing of the British contract is explained in part by the fact that they have no wagon mines and, in fact, few mines with an annual capacity of less than 50,000 tons. This means that all the producers are men of substance. Even allowing for that, all the American observers agree that business honor in Great Britain is on a very high plane.

### Exchange a Steadying Influence

One of the things which contributes to the maintenance of the settled relationships in the British trade and the high standard of honor is declared to be the coal exchange. There are some fifteen such exchanges in the principal cities of the British Isles. That at Cardiff is typical. Through this exchange and similar ones at other South Wales ports, arrangements are made for the marketing of the 50,000,000 tons which are produced annually in this section. The floor of the exchange is a busy place for two or three hours at the middle of the day.

Representatives of the producers, the middlemen, the shipowners, the insurance companies, and in fact, all having anything to do with the coal trade initiate most of their transactions

through personal contact on the floor of the exchange. It is not unusual for an exporter to receive an order from abroad, arrange the purchase of the coal, procure the vessel and arrange the insurance all within an hour, without leaving the floor of the exchange.

The larger exporting firms have their own docks. Their foremen call at the exchange each morning and are given instructions as to the loading of ships. There is no posting of sales with tonnage and prices, and no preliminary investigation of an applicant for membership. Membership on the exchange can be maintained only, however, by the strict observance of its traditions of square dealing. The Americans were convinced, however, that the personal contacts at the exchange are an important element in building up a high standard of business honor.

### Verbal Promises Are Always Kept

Agreements made verbally on the floor of the exchange are leisurely confirmed later by letter, but over a period of many years there has been no instance when a member has failed to keep his verbal promise, regardless of price changes that may have resulted before he committed himself in writing. While there is no blackboard in the exchange, the representatives of the trade papers are admitted to the floor and base their bulletins of prices on the transactions which are made on the floor.

Observers from the United States are convinced that these exchanges contribute to a more prompt handling of business than would be possible without them and that they contribute in an important degree toward the stable relationships and square dealing which characterize all factors in the coal trade in Great Britain. There is frank recognition that each factor needs the other and the veiled hostility which so frequently characterizes the relationships between American producers, wholesalers, retailers and the transportation agencies is entirely lacking.

There is much difference of opinion, even among the Americans who have visited the British exchanges, as to whether or not this institution could be used to advantage in this country. There is no one place in this country which can be compared to Cardiff, where so large a portion of the output of the tributary region flows through one channel. Norfolk and Cleveland are the only points where conditions are at all similar. In the coal fields tributary to those two points, only a part of the production is water borne. A very considerable portion of the output moves by rail from hundreds of mines to thousands of destinations. This greatly reduces the advantages of

## Best Wages and Conditions In America, Says Kennedy

Special to *Coal Age*

Scranton, Pa., Sept. 23.—The highest wages and the best working conditions in coal mines are found in America, Thomas Kennedy, president of District 7, United Mine Workers, recently declared upon his return from a tour of Europe. Accompanied by James A. Gorman, secretary of the Anthracite Conciliation Board, he visited Europe as one of the delegates from the organization to the International Mining Congress at Prague, Czechoslovakia. Mr. Kennedy is now attending sessions of the biennial convention of the miners of the Lehigh field at Freeland. Neither he nor his staff, except members of the district executive board, had opposition for another two-year term at the election held recently. During Mr. Kennedy's absence, Andrew Matti, veteran vice-president of the district, was in charge of affairs. Matti is the oldest official of the United Mine Workers in the anthracite field, having taken office soon after the men were organized by the late John Mitchell.

the coal exchange, even at those unusually favored points.

At the same time the coal exchanges at interior points, such as London and Sheffield, seem to possess great vitality, despite the fact that they are not the active institutions as are the exchanges at Cardiff and Newcastle. Much of the business at those points is conducted, as it is here, by telephone, by mail or by personal solicitation, yet the exchange apparently performs a valuable function in addition and some think that the plan is well worth trying at such points as Pittsburgh, Columbus and St. Louis.

## Shirkie Denies There's Foul Air in His Mine

Hugh Shirkie, owner of the Shirkie mine at Shirkieville, Ind., which is idle because of a strike of the miners employed there, stated that the miners' allegations of foul air and no roads are without foundation and that in support of his statement he has the official statement of the mine inspector.

In a resolution the 500 miners gave as their reasons for refusing to work that foul air in the mine had resulted in one death and serious sickness to another miner, and that the company had failed to provide proper tracking, causing 90 per cent of the miners to have to shovel their coal several times before finally reaching the mine car with it.

The resolution stated that J. W. Davis, a negro, died at the top of the mine on Aug. 19, after coming out of the mine, because of foul air, and that on the following day 65 miners were forced to abandon work because of foul air in the mine.

## Problems In Underground Management

### Underground Locomotive Barn at Kramer Both Capacious and Convenient

**T**HE ultimate economy of commodious and well constructed quarters for the storage and repair of mine locomotives is now quite generally recognized. The problems involved—and indeed, they are not easily solved—are most vital. Time was when a structure of this sort was viewed as a luxury, but no longer is this true, for the motor barn is now a primary part of a mine operation.

The satisfactory location of an inside locomotive barn and the arrangement of the stalls and track, not to mention the coursing of the ventilating current through the barn and the layout of the repair pit, call for careful study and the revision of many details before actual construction commences. The plan of the motor barn of the Northwestern Mining & Exchange Co., Du Bois, Pa., for its new Kramer mine—daily capacity 4,000 tons—is suggestive of possibilities in such construction.

This barn is to be located 600 ft. from the auxiliary shaft. The first stall looking inbye, is the largest and is provided with a pit and such equipment as will be required for making minor repairs to locomotives. The second stall is planned for the unloading of supplies from mine cars into a wide crosscut at the rear of and joining the

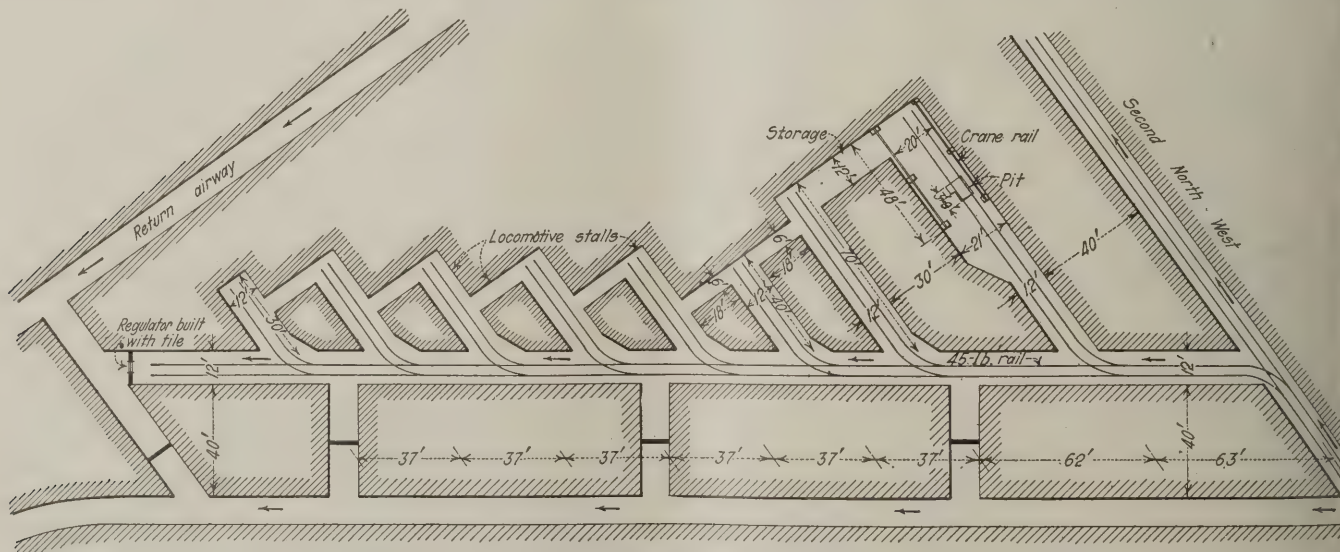

#### Cross-Section of Repair Pits

The mine rail is supported over the repair pit by shelf brackets. By this means the width of the pit is not limited as it would be if the rails rested directly on the tops of the walls on either side of the pit, nor do the rail supports hamper the work of the electrician.

first and second stalls. This provision obviates the need for storing supplies and materials where they interfere with the workmen. All other stalls are to be used for the storage of locomotives; each will accommodate three 13-ton units, except the last, which has room for only two locomotives of this size.

Crosscuts are to be made from stall to stall to facilitate ventilation. It

tially built of concrete and steel. Attention is called to the most important features—namely, the crane and the pit. To provide facilities for lifting parts in any part of the stall, a 5-ton crane of the trolley type will be provided. The track by which it is supported is strong enough to sustain the weight of one end of a 13-ton locomotive when it is necessary to tilt the machine so as to facilitate the removal of

#### Underground Locomotive Barn at 4,000-Ton Mine Provided with Several Stalls

Each stall except the last holds three 13-ton locomotives. The end one has capacity for two only. The first, or outbye, stall has a repair pit and equipment for

making minor repairs. The second stall is used for the unloading of repair supplies from mine cars. The arrows indicate the direction of the air current by which the

barn is ventilated, provision being made for throttling the ventilation should it at any time prove excessive, especially in the winter months.

wheels or tires. The crane track, which is supported by 15-in. I-beams running lengthwise of the repair stall, is 48 ft. long, each track resting on two 24-ft. lengths of I-beam, which in turn rest on three concrete columns, the joint between them being supported by the center column.

The locomotive track rails over the pit rest on shelf blocks. Thus working space is provided under and around the tracks. The stairway, which is of concrete, enters at the side of the track. Consequently it in no way reduces the available operating space. In these two ways the electrician in making his repairs finds his movements and efforts unhampered.

## Passing of Mine Bosses' Underground Shanty

By C. E. REYNOLDS

Superintendent, Allegheny Pittsburgh Coal Co., Logan's Ferry, Pa.

Underground mine bosses should meet several times each working day to compare notes and talk over the work of the day. An office of some sort is usually provided in the mine for this purpose. More often than not it is nothing more than an enlarged manhole in the coal, which is sometimes boarded off from the entry on which it faces and is entered through a flimsy door; it may or may not have a window. Because of its crude construction and make-shift appearance, it is generally termed the "bosses' shanty." But times change. The company office of prior years was crude compared with that of today, and underground offices doubtless will share in the general advance.

In the Springdale mine of the Allegheny Pittsburgh Coal Co., not far from Pittsburgh, a fireproof office of concrete and steel is being completed that has the appearance of a carefully planned outside building. It was built with the purpose of making office hours pleasant for the bosses, thereby insuring greater efficiency from them. An interior view of this office is exhibited in the accompanying illustration. The

wires attached to the two-by-four in the left-hand corner are temporary.

This office is located in a break-through between the manway and the main haulage road. At each end is placed a door to give easy access to, and to give a good view of, each entry and in each of the endwalls is a port-hole that sets up a ventilating current of air in the office. Conveniences in the form of an electric stove and built-in clothes lockers are furnished. The company plans later to conduct from the outside drinking water and hot water for washing to a point on the manway outside the door of the office. At this station also it intends to install latrines that will be discharged into a sewer line leading to the main sump which has a storage capacity of over 2,000,000 gal. of water.

## British Make New Rules for Safety in Shotfiring

The British Secretary of Mines has issued an order, to become operative on Oct. 1, governing the firing of shots in coal mines where danger may arise from firedamp or coal dust. The new regulation stipulates that no person may be newly appointed to fire shots unless he possess the prescribed qualifications as regards age and practical experience underground, and that no person may be appointed whose wages depend upon the mineral to be gained.

The examination for gas, which has to be made by the shotfirer immediately before the firing of each shot, is to include examination for any gas issuing from the shothole itself and from any break within 20 yd. Shotfiring is specifically prohibited within 20 yd. of cavities and breaks that are not accessible to examination for gas issuing from them or contained in them.

Every place where a shot is to be fired is to be treated thoroughly with stone dust or water unless the firer is given written permission by the manager to dispense with this precaution. Where two shotholes are close enough together to make it possible for the firing of one shot to relieve the work

to be done by the other, the first shot must be fired before the second hole is charged, the object being to guard against the second hole being overcharged, as might be the case if it were charged before the first shot were fired, leaving the firer in doubt as to the work to be done by the second shot. An exception with limitations is made to this provision in respect to shots to bring down the coal in longwall faces, subject, however, to the condition that the shots are fired between shifts.

## Wetted Handkerchief Useless As Breathing Apparatus

According to A. T. Winborn, in the *Ebbw Valley Works Magazine*, mine workers in South Wales are being taught to use a handkerchief as a respirator in mine-rescue work and, further, when examined at ambulance (first-aid) competitions they lost marks if they omitted to make reference to its use in emergencies.

Mr. Winborn remarks that the only possible service a handkerchief might perform would be to filter air containing dust or smoke and thus lessen in some degree the irritation that is caused to the bronchial tubes and other air passages when air is breathed under these conditions. In the case of smoke, however, says Mr. Winborn, one would be well advised to use caution, as smoke is rarely unaccompanied by noxious gases which easily might overcome the man placing his full confidence in the handkerchief.

### HANDKERCHIEF FOR SELF-SUCCOR

In comment on Mr. Winborn's remarks it may be said that the use of a wetted or unwetted handkerchief in safety work is wholly inexcusable. The risk is too great. The handkerchief is no protection against carbon monoxide. It has its uses, however. Where the hazard has to be faced by a man caught in a mine after an explosion it is advisable to use a wetted handkerchief, which will screen out the smoke and dust in the air he breathes, which solid particles may well be poisonous. It is not to be forgotten that men have been poisoned cleaning out byproduct apparatus at coke-oven plants where carbon monoxide most probably was not present.

The smoke and dust may not be harmless, and it is well to screen it out. Probably carbon monoxide in lethal doses will be present. If it is, the handkerchief is no protection except as it hampers respiration and so lengthens a little the time in which the blood will become saturated. We do not know, furthermore, that there are no highly soluble gases that the water in the handkerchief may absorb.

The handkerchief has done excellent work apparently in some cases, but to use it in rescue operations is to take a chance that cannot be too strongly condemned. Those who are in the mine and face immediate death, however, would do ill not to use any method that might be of assistance, no matter how relatively ineffectual, and there is some reason to believe that to use a wetted handkerchief is better than to take no precaution against death.

How Long Will Your Mine Run?

If for many years, it will pay to build a comfortable, spacious office underground, electrically lighted, cement faced, with lockers and other conveniences like this one at Springdale, Pa.

## Practical Pointers For Electrical And Mechanical Men

### Uses Electrically Heated Oven to Keep Equipment Dry

It is indeed unusual to find a repair shop so well equipped as that at the Orient No. 2 Mine of the Chicago, Wilmington & Franklin Coal Co., near West Frankfort, Ill.

Like many other parts of the plant the electrical repair shop shows evidence of a tendency to break away from customary mine practice. An interesting feature of this shop is the automatic electrically-heated baking oven. This heater is used for drying electrical apparatus after or in process of repair, and it may be used to dry electrical insulation, which, for instance, has become wet by being splashed in water

as to what could be done. He had undergone such disagreeable experiences before. Perhaps he could smooth the ring a little with a block of stone and continue to put in new brushes to replace those being rapidly worn out. In this way he might postpone permanent repairs until Sunday, but at a considerable cost in brushes, labor, anxiety and wear to the collector ring.

Suddenly a new idea came to him. What would happen if he would remove all the brushes that bore on the bad ring. After an hour's thought and study he was thoroughly convinced that, in view of the light load on the

six-ring converter, the machine may sometimes refuse to start from a standstill. However, by turning the armature to another position and then closing the alternating-current starting switch, the machine would start without hesitation.

### Let Repairmen Know What Replacements Cost

Typical of the progressiveness of the Mallory Coal Co., of Logan County, West Virginia, is the method used in handling the mechanical and electrical repair parts. Upon stepping into the warehouse a display of white tags catch the eye. These tags are tacked below each of the well-arranged wooden bins and tied to the larger and heavier parts that are stored in orderly fashion on the floor.

An examination of these tags reveals that in addition to the usual information regarding catalog number, order number, and description, the unit cost price is given in plain figures, for any one to read. By this method the chief electrician and others taking out repair parts are informed as to the cost. As this class of parts usually costs considerably more than the repair men realize, the system has the effect of making the conscientious man hesitate before using a new part, and often induces him to put back into service an old part which by a little ingenuity and work can be made to serve as well as the new.

The company may have other reasons for noting the cost prices on the tags. Whatever these may be it is apparent that the practice does not add an appreciable extra burden of clerical work. The receiving, accounting and dispensing of supplies is handled with a surprisingly small expenditure of labor.

**Electric Baking Oven with Automatic Heat Control**

Electrical apparatus which must be held as spare equipment often absorbs moisture from the air and when most needed proves to be unserviceable. This oven can be regulated to maintain any desired temperature. It would be a valuable acquisition to any mine-supply or repair shop.

or has been idle and, in consequence, has absorbed moisture. Devices for the automatic control of the oven maintain a constant temperature or shut off the heat at any predetermined time.

### Removes Arcing Brushes and Runs Without Them

The alternating-current brushes in one holder of a six-ring, 300-kw., 275-volt converter began to flash indicating a burned spot on that particular collector ring. Although the average day load was not over 150 kw. this ring was rapidly getting in worse condition. It was inconvenient to stop the converter for repairs before the next Sunday. The mine electrician was puzzled

converter, this was the only reasonable way to meet the difficulty. A trial proved his judgment correct. The machine carried the load until the next Sunday with no signs of distress. When Sunday came the ring was put into first-class condition by turning and grinding.

The method of "getting by" with removed brushes having proved successful, this mine electrician wondered what proportion of the full load could be carried under such a condition. From a reliable technical source he was informed that approximately 58 per cent of full-load rating could be safely carried by the converter. In addition he was informed, and it was later proved by trial, that when the brushes are lifted from one ring of a

### Purchased Expensive Lathes Without Due Thought

A company decided to buy several engine lathes, one for each repair shop. Someone suggested that these lathes should be large enough to turn the tires of the haulage locomotives. In the office a catalog was consulted showing the largest tires to be of 30-in. diameter. Lathes accommodating a 30-in. circle were purchased and installed, but when, several months later, an attempt was made to put an axle with wheel cores and tires assembled, into one of these lathes it was a shock to find that a 30-in. tire is of 30-in. diameter at the tread but considerably more over the flange. The lathes were useless for this important duty.

A similar case occurred with another company. One of the officials appropriated money for a new lathe. The management of this company also thought it advisable to get a lathe large enough to accommodate locomotive trucks. An expensive gap or double-bed type lathe was specified, the maximum gap opening to be 40 in., this being the gage of the locomotives. Soon after the installation an attempt was made to put a truck in the lathe, but the gap was not wide enough. Too late it came to the attention of the purchasing agent that a 40-in. gage truck measures more than 40 in. width over tires. The lathe has never been used as intended.

What is the lesson? Just who was at fault? We will not try to place the responsibility but suggest that had the practical mine mechanic or electrician been taken into confidence and consulted regarding the details of the lathe to be purchased, the errors would not have occurred.

## Plug and Hose Always Ready

Regardless of all the precautions which may be taken at a mine property to eliminate the possibility of a fire

Fire Hose Protected from Weather

So that the fabric will not become wet and rot and also to prevent the heat of the sun from injuring the rubber the fire hose is protected by a small slanting roof. The sides of the housing also support a reel upon which the hose is wound.

not a little hazard still exists. Buildings of concrete, stucco or steel make the mine yard quite safe; however, the very nature of some of the equipment and supplies which must be kept in the yard makes it imperative to have fire-fighting apparatus always available.

Fire plugs and reels of hose are located in several advantageous positions in the yard of Donk Bros. Coal and Coke Co. Thermal mine No. 4, near Edwardsville, Ill. The fire hose is always handy and to protect it from the weather is covered with a little housing as shown in the illustration. The hose is on a reel, so it can be run out readily.

## Hoisting Cables Should Be Lubricated Regularly

Most wire ropes used for hoisting purposes are constructed with a core of manila heavily saturated with a good lubricant. The strands of steel are wound around this core which acts as a cushion and holds the grease or lubricant in reserve. This does not, however, obviate the necessity for the subsequent use of a lubricant after the rope has been placed in service.

The illustration shows workmen at the J. K. Dering Coal Co. Mine, near Eldorado, Ill., lubricating the main hoist cable. The work is done periodically so as to insure proper service and long life from the rope.

The men are shown on a wooden platform laid across the shaft opening. After the attachments between the rope and cage are lubricated the cage is slowly lowered to the bottom of the shaft. The men on the platform meanwhile apply grease to the rope. Cloth gloves are used for this work so that the workmen will not injure their hands on any broken or damaged wires.

All this work must be done carefully because just below the men, under the temporary platform, is the gaping hole of the shaft. As grease may drop on the platform where the men might step and slip much care is taken. It must be remembered that with greasy gloves and no place on which to hang every precaution must be taken to avoid the possibility of an accident.

When planks are stretched across the shaft for this kind of work the ends should not extend over the opposite compartment, because when the cage in the compartment over which the men are working arrives near the bottom the other cage may come up and strike the ends of the planks and upset the men into the shaft.

Usually nearly all of a hoisting cable may be lubricated from some position near and over the ground. Often this may be done where the rope enters the hoist room or inside the building just where the rope passes onto the drum. Here the workmen are safer.

Greasing the Main Shaft Cable

Hoisting ropes must be lubricated frequently, but, as the work is dangerous, precaution must be taken so that the workmen may not be injured. These men are standing on a temporary platform.

## Gasoline Locomotive Hauls Cars Around Mine Yard

Not all the locomotives used at the mines are operated by electricity, steam or air. At the Orient No. 2 Mine of the Chicago, Wilmington and Franklin Coal Co., near West Frankfort, Ill., a gasoline locomotive is used to transport cars around the colliery yard.

It was chosen for this service because it was desired to keep the yard free from trolley wires. All the cables and wires around the buildings are buried. The power used in the shops and supplied to the large shaft hoist which incidentally is the largest in the coal-mining field, is furnished through underground cables laid in extensive conduits leading from a main transformer substation.

Gasoline Locomotive Obviates Need for Electric Wiring

Mine yards nowadays are being laid out so that every operation may be performed rapidly and with ease. Former generations delivered themselves of a similar "wheeze," but witness the gasoline locomotive used at Orient No. 2 Mine. As it eliminates trolley wires it makes it unnecessary for the top men to keep looking up to watch their heads. When they should be looking downward to watch their steps.

## Book Reviews

### Heating and Ventilating Engineers Fail to Sense Some Big Opportunities

Regret will be the principal sentiment of the coal producer who reads "The American Society of Heating and Ventilating Engineers' Guide, 1924-1925." The book contains so much of great value, is such a credit to the society that issues it that a coal producer cannot but be surprised that it overlooks in such a marked degree the two big needs of the heating and ventilating industry—the cooling of air and the use of small coal.

It is to be hoped that when the title is changed so as to read "1925-1926" the book will contain two new chapters on these subjects and will treat them with as much completeness and acumen as it does the others and that the advertising section will bear evidence that the heating and ventilating engineers have these two desiderata in mind. There is a chapter in the present book on refrigeration, but it deals with cooling not so much for human comfort as for the preservation of perishable products.

A chapter on "How Temperature, Humidity and Air Motion Affect Human Comfort" does get measurably nearer the subject. We are informed that "the cooling effect produced by the evaporation of water has been helpful in air conditioning, particularly when the air is quite dry." Unfortunately we want the air cooled most when it is most highly saturated, and so this statement gives a minimum of satisfaction. However, the value of air movement is stressed, but the breeze helps in no degree when the air is entirely saturated. It seems that comfort may be increased, but real comfort cannot be attained, through evaporation.

We think heating and ventilating engineers will some day arrive at the point where they will give us comfortable air under the most humid of conditions, not alone by air motion and evaporation of water but by actual cooling provisions.

As for the other deficiency in this book it is inexplicable. We look at the advertisements with a hope born of despair. Surely the boiler manufacturers, if not the heating and ventilating engineers, realize the importance and advantage of using fine coal, especially those exhibiting in the economy shows of the anthracite operators. A few do, apparently—in a degree.

The Brownell Co. says: "The Brownell Smokeless Boiler is designed and constructed to burn any kind of fuel economically and without smoke," but it says no more. The Abram Cox Stove Co. is a little more specific. It says: "The cheaper grades and sizes of hard coal are made to yield as many heat units as the larger and more expensive sizes. In the Novelty Carburetor Boiler there is a big saving in burning hard coal regardless of the size, as well as soft coal."

The International Heater Co. says: "The International Economy Smokeless Boiler is an updraft boiler designed to burn any fuel used for heating purpose, as soft coal, hard coal including buckwheat on large installations, coke and oil." "The Molby Boiler," says the Molby Boiler Co., "gives a steady, even heat over long periods with low-priced No. 1 Buckwheat anthracite."

The Spencer Heater Co. briefly claims that its boiler "burns small-size hard coal." Most of the advertisements say nothing whatever about coal size. The Combustion Specialties Corporation, manufacturer of the Combustio Draft System and an exhibitor in the anthracite economy shows, says nothing about the ability to burn small sizes.

We think the anthracite and bituminous operators should suggest to the manufacturers who make boilers which are able to burn small sizes that they stress that fact in their advertisements. We believe they should urge on the Heating and Ventilating Guide publishers that some statement be made in the text on the lower price and greater economy of the use of small sizes of coal. No subject is more important to consumer and producer than this of the possibility of reducing the size of coal burned. Missionary work is best done in guides, text books and publications that the architects and ventilating engineers read.

### Neglect Economy of Small Sizes

A word to publishers who may be expected to issue such books doubtless would suggest to them the advantage of their authors specifically calling attention to the economies in using smaller and less expensive coal, not with the design of inducing authors to introduce what they do not approve—if it be possible that they do not approve of the use of fine sizes—but so that a matter so vital shall not be overlooked. No book on heating is complete that does not emphasize this feature in modern practice.

The Guide contains 234 reading pages, 224 pages of catalogue advertising and 52 pages of the roll of membership in the society. It measures 6 x 9 in., is cloth bound, costs \$3 and is published annually by the society at 29 West 39th St., New York. To quote its authors, it "contains reference and design data useful in the planning and construction of modern heating and ventilating installations, prepared from the society's transactions, the investigations of its research laboratory and the practice of its members." The statement is a modest definition of an extremely useful book. Frederick D. Mensing and the Guide Publication Committee are greatly to be commended. More might have been said in this volume about the controversial subject, methods of combustion, but perhaps lack of space and a desire not to enter into controversy caused this subject to be avoided.

### Byproduct Coking

An excellent book but somewhat too closely devoted to British practice is that by the late G. Stanley Cooper and Ernest M. Myers. It is entitled "Byproduct Coking." We say it is British primarily because it says nothing about the Roberts oven which has done so much to revolutionize American coking possibilities by making it possible to make coke out of Illinois coal. It says nothing about American practice with its short coking time and high temperatures. It seems strange that the latter subject is untouched, for a remarkable paper on the advantages of American practice has been published in most or all of the British papers which make coking a subject for attention.

### SPEAK A COMMON LANGUAGE

Nevertheless the practice in the United States is confessedly based on European practice and Coppée, Otto, Simon-Carves, Koppers, Semet-Solvay and Wilputte are almost household words among byproduct-coke men in the United States, though Collin, Huesener and Simplex and the company which is named, Coke and Gas Ovens, Ltd., are not by any means so generally known. The brief preparation section of this book is, however, wholly alien to our practice and describes nothing but Coppée and Baum (Simon-Carves) washers. Readers will be interested in one reference to American practice which seems to indicate one of the reasons why byproduct ovens are not placed at coal mines, though another and perhaps more important reason is because there is little opportunity to use the gas, unless the mines are near a town or a large blast furnace where the gas can be used for domestic purposes or for engines as the case may be.

"In Great Britain" says one of the authors, "little has been done in the way of scientific mixing of various classes of coal, but in America coal mixing is much resorted to, and the mixtures are so arranged that a coke is produced suitable in all respects for American blast-furnace practice. Coals from several districts are thoroughly combined in special mixing chambers, the proportions of each being previously determined as a result of careful tests and comparisons. These chambers serve as receptacles for the different coals, and mechanical means are provided to insure thorough admixture and the production of a homogeneous coke. This mixing is the key to the success of the plan."

The book deals with the oven itself and its operation, with the machinery by which the coal and coke are handled and the gas exhausted, the recovery of tar, ammonia and benzol, condensers and scrubbers, utilization of surplus coke-oven gas, tar distillation, chemical tests and the future developments of the industry. It contains 192 pages measuring 5½ x 8½ in. and 131 illustrations, including 18 folded plates. Cloth bound. Price \$4.50. The American publisher of this Benn Bros.' book is D. Van Nostrand Co., 8 Warren St., New York City.

# Production And the Market

## Demand in Bituminous-Coal Market Gaining Accompanied by Better Prices

Stimulated by the seasonal urge of cooler weather, the bituminous-coal trade continues to show the steady advance that set in a few weeks ago. Prices are still climbing, the gains being due almost entirely to the increasing demand for the larger sizes, quotations for slack showing a marked downward tendency. The process of readjustment in general industrial conditions is still in evidence, and as a result consumers are buying carefully. Nevertheless, hitherto tardy buyers on contract are reappearing here and there and signing up. With the acceptance of a 10-per cent cut in wages by 14,000 textile workers resumption of operations on full time in a large number of New England plants that have been long idle is announced for Oct. 1. Meanwhile other industries report increases in employees, payrolls and earnings per capita.

### Price Index Advances Again

Coal Age Index of spot prices of bituminous coal continues its upward course, advancing two points during the last week to 169 on Sept. 22, the corresponding price for which is \$2.04. This compares with 167 and \$2.02 respectively on Sept. 15.

A further increase in activity was in evidence at Hampton Roads last week, dumpings of coal for all accounts for the seven days ending Sept. 18 totaling 383,710 net tons, compared with 338,432 tons handled during the preceding week.

Although the movement of coal up the lakes has declined markedly from the peak reached during the last week in August, total shipments being nearly six million tons less than at this time a year ago, the carryover of four million tons from last year must be considered in any estimate of the adequacy of the available supply. There was practically no carryover from 1922 to 1923. Dumpings during the week ended Sept. 21, ac-

cording to the Ore & Coal Exchange, were as follows: For cargo, 770,331 net tons; for fuel 45,957 tons, compared with 705,606 and 42,598 tons respectively during the previous week.

### Sharp Increase in Output

Production of bituminous coal registered a sharp rebound during the week ended Sept. 13, when, according to the Geological Survey, 9,531,000 net tons was produced, a gain of 573,000 tons over the week ended Sept. 6, when the output was 7,958,000 tons, according to revised figures. The comparatively low total of the

previous week, of course, was due to the short week occasioned by the observance of Labor Day. There also was a marked increase in the production of anthracite during the week ended Sept. 13, the output totaling 1,820,000 net tons, compared with 1,451,000 tons during the preceding week.

The anthracite market continues to gain headway, tonnage moving with increasing ease. Stove maintains the leadership in demand, but egg and nut are moving more rapidly. Steam sizes likewise are gaining in strength. Independent quotations for domestic sizes show a growing firmness.

### Estimates of Production

(Net Tons)			
BITUMINOUS			
	1923	1924	
Aug. 30	11,737,000	8,719,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Lump Up; Steam Down

Stiff demand for domestic sizes of the best Midwest coals continues but a softening of the weather is expected to produce a quieting effect. In fact this effect is already beginning to make itself felt in central Illinois and in the Standard district. Business is heavy enough even in those fields, however, to keep every open mine running most of the time. No further increase in lump and egg prices is expected soon in those regions. East Kentucky and West Virginia business in the Midwest continues so pressing that producers are declining orders for domestic sizes. Smokeless lump is now solidly fixed at \$4, and mine run, though still running at \$2, may take an overdue rise by Oct. 1.

The inevitable result of all this rush of domestic business is a slump in steam coal in most fields. Good southern Illinois screenings several days ago sank past their previous bottom of \$1.50 and now range clear down to \$1.25. Central Illinois steam coal runs down to \$1.10 and Standard district is well below \$1. This means that practically everything won in higher domestic prices is lost on screenings. No car shortage of any serious proportions has developed in the Midwest fields but the Illinois Central felt the pressure sufficiently to begin on Sept. 15 counting "no bills" as empties. Other roads did not follow suit last week. However, Illinois Central mines are not heavily burdened with

"no bills," even in steam sizes, so nobody is suffering much from the order.

Mines in the Duquoin and Jackson County field are working and coal is moving, with the exception of nut and screenings. Three days a week seems to be the limit in these fields. In the Mt. Olive district domestic tonnage is beginning to move and things are opening up. Nearly all the mines have a couple of days a week with steam sizes going on contracts and railroad tonnage good. In the Standard district, steam is holding back working time. Screenings are hard to move and steam nut and egg are impossible. Six-inch lump and 3x6-in. egg are in fairly good demand and 2-in. lump is beginning to move. Mines here are getting three to four days a week and could do better were it not for steam sizes.

In St. Louis the first chilly wave brought the business that should have come to the dealers two months ago. Nearly all of this demand is for lump coal and has occasioned an advance of 50c. a ton in two weeks. Dealers are asking the same price for egg as for lump, even though they can buy egg for 25c. a ton less. Business seemingly is going to southern Illinois high-grade this season. The retail price on this advanced from \$6.75 to \$7 with prospects of a further advance in a day or two. Mt. Olive, which has not begun to sell yet, advanced from \$5.75 to \$6. Standard remains at \$4.75@5.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	Sept. 22	Sept. 15	Sept. 8	Sept. 24
Index .....	169	167	166	200
Weighted average price....	\$2.04	\$2.02	\$2.01	\$2.42

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

### Kentucky Is Oversold

Demand for coal in Kentucky is quite heavy. Many operating companies are sold up, running full time, and refusing business that doesn't carry a good price. The result is that prepared quotations are 25 to 50c. a ton higher than they were a week ago. Western Kentucky producers are asking \$2.75@3 for best block, while eastern Kentucky operators are going them one better and quoting \$2.75 @ \$3.25. Lump is \$2.50@2.75 in both fields, with egg moving at the lump price in western Kentucky, and about 25c. a ton under lump in eastern Kentucky. Mine run and screenings are practically unchanged.

The better prices and steady demand may influence a few small companies to sign the Jacksonville agreement in the strike zone of western Kentucky, one large company having given in over the week. However, the operators whose mines are down on account of the strike, are generally figuring on being down for years, instead of months, unless they can go on a non-union basis or "bust" the union. Right now, however, it looks as if the producers can sell all the coal they can mine, and at excellent prices.

### Northwest Is Busy

Receipts at the Duluth docks fell off last week, when only 33 cargoes were landed, and of these, five were hard coal. Twelve cargoes are en route and one of these is hard coal. It is thought that receipts will gradually fall off from now on, as the grain trade is rushing and the docks are fairly full. The dock companies evidently are not figuring on carrying a large surplus over after the close of navigation.

The 28c. increase in rates from southern Illinois mines to Twin Cities has been confirmed by the Interstate Commerce Commission and Duluth dealers expect more Twin City business as a consequence. The hard-coal movement is large, although a warm spell which started last Wednesday may stop shipments. Country dealers say that they fear a rail tie-up and hope to turn over quickly the stocks they are ordering. Soft coal is moving well, although there is no rush. It might be termed normal business. The docks are shipping steadily.

Milwaukee coal dealers are more buoyant in spirit. Orders are flowing in, and coal is moving from the docks. There is a notable tendency toward firmness in prices. Southern Illinois mines have advanced their figures 15 to 25c. a ton to dealers and the Pocahontas mines are not taking orders because they are well sold up. Milwaukee dealers expect an advance in Pocahontas of 50 to 75c. a ton. The total receipts of coal at Milwaukee by lake thus far in 1924 are 552,954 tons of anthracite and 1,488,310 tons of bituminous coal.

### Western Business Is Quiet

The demand for Southwestern production has improved steadily since Sept. 1. Mines already open are working almost full time and more mines are expected to be reopened in Kansas soon. The quotation on Henryetta (Okla.) lump has been advanced to \$5.50. Oklahoma nut is quoted at \$4, mine run at \$3.25 and screenings at \$2. Kansas shovel lump coal has been advanced 25c. to \$4.25. The prices for other grades of shovel coal are the same as those for shaft: \$4 for nut, \$3@3.50 for mine run and \$2.35 for screenings. Present quotations show a cut of 15c. on screenings, which have shown a tendency to move more slowly than domestic grades, although there is no surplus yet.

Last week was rather dull throughout Colorado, which resulted in a notable decrease both in the production and working time of mines. However, during the last few days the heavy demands for all sizes have been encouraging and operators are preparing for a busy season to begin soon. Colorado mines worked on an average of 25 hours last week and less than 30 per cent of working time lost was attributed to "no market." Prices remain unchanged.

In Utah mines are still operating less than three days a week. They are shipping more coal to the Northwestern markets than they were, but the demand from the Pacific Coast is poor. Very little business has been obtained by the Utah operators in this market since storage orders were filled about the middle of August.

### Sellers' Market at Cincinnati

For the first time in ten months the situation at Cincinnati has changed from a buyers' to a sellers' market. Most offices have available supplies well booked to the end of the month. Buyers from Cleveland, Toledo and other lake ports have appeared in quest of slack and the smaller sizes. Two-inch has stiffened and domestic holds firm. In smokeless there has been a general disposition to move the domestic price up to \$4. The run of mine business in low volatile is acceptable at \$2 and there isn't much stuff moving under that. The slack is the weak brother. Because of the large call for the sized coals there has been a perceptible weakening in the Western movement.

Domestic trade in Columbus and central Ohio shows a decided improvement. Buying of the better grades has resulted in higher prices on smokeless and certain varieties of splints. Industrial conditions are improving, though steam buying is restricted to present needs, some of the larger consumers still using up reserves. Contracting is quiet. Utilities are fair purchasers while carriers are buying less than normal. Production is showing slight increases in all producing areas of Ohio.

The steam trade at Cleveland seems to be moving along in alternate waves of strength and weakness, though a steadily increasing demand is evident, and spot prices are holding firm at recent quotations. Inquiries are fair and steam purchasers are buying moderate quantities, both for current needs and storage. Many mines in eastern Ohio report car shortage on one large railroad, due to open-top cars being on other divisions of the road and the further fact that repair work on bad-order cars has been deferred until their need was imminent. The railroads report increased traffic and there is a better tone all around, business conditions showing improvement.

### Tonnage Moving Better at Pittsburgh

Coal movement out of the Pittsburgh district has increased slightly in the past week or two. Measured by conditions in the steel industry, there has been no increase in industrial activity since Sept. 1. Some consumers are now stocking coal in a limited way, however, the liquidation of old stocks having been practically completed several weeks ago. The call for domestic coal is slowly rising.

Further improvement is noted in central Pennsylvania, but the increase in output is not large. Wagon mines are picking up business for delivery to the cities and the car loadings for the week ending Sept. 13 were 13,120, as against 10,818 for the previous week, which had one holiday. There are 1,800 "no bill" cars.

The general tendency in the Buffalo market is still a stand-off, there being slight improvement if anything. Quite a large percentage of West Virginia coal is coming in, paying 15c. a ton freight over Pittsburgh and still able to come out whole some way. Regular quotations remain at \$2.25@ \$2.50 for Youghiogheny gas lump, \$2@ \$2.25 for Pittsburgh and No. 8 steam lump, \$1.75@ \$2 for all mine run and \$1.10@ \$1.35 for slack, paying \$2.09 from Allegheny Valley mines and \$2.24 from other mines for freight to Buffalo.

Industrial conditions at Toronto show little change, the demand for bituminous continuing light. Quotations for carload lots f.o.b. destination are: Steam lump \$6@ \$6.40; Pennsylvania smokeless, \$5.75@ \$6.25.

### Weakness Reappears in New England

The firmer tendency noted in the New England tidewater bituminous market last week has not been maintained and a weakness even more pronounced than heretofore has developed. To move an oversupply certain shippers have named \$5.15@ \$5.20 per gross ton on cars Boston for what is claimed to be Pool 1 run of mine New River and Pocahontas and orders have been acceptable at this level regardless of the amount ordered. There has been no decline in spot f.o.b. prices at the southern loading piers for strictly high-grade coals, however, \$4.10 being the minimum and up to \$4.30 asked in certain instances.

The all-rail market offers nothing new. A few inquiries have come forward but they have not resulted in business because prices cannot be made to compete with the landed cost of coal from tidewater.

The Providence tidewater market maintains a higher price level than Boston. Some early-week sales were at \$5.25 on cars for pool 1 mine run New River, but this was to clean up cargoes and \$5.30 is now the low quotation, some business being done at 5c. to 10c. more. Arrivals have been fairly plentiful the past week but as most of it has been in barges shippers have not been under pressure.

The retail demand for anthracite has expanded considerably.

### Atlantic Markets Slowly Gaining

Business at New York during the past week has not been as brisk in some quarters as the previous week, though receipts move easily. Some new business in contracts extending to April 1 was reported, but seller and buyer negotiate carefully. A firmer tendency is evident and the prospects for a busy late fall and winter are bright. Large consumers are willing to take more coal and it is not as hard as formerly to ship full quotas on contracts. The railroads are taking heavy tonnages and buying by various industries has been heavier. Receipts at tidewater piers are moderate and there is not as much free coal to be picked up at low prices.

Movement of tonnage at Philadelphia is increasing, but it is far from sufficient to enable mines to operate on full time. Producers are not at all keen in making contracts except at considerable advance on present market prices. Business conditions continue to improve, and consumers are taking more tonnage for storage, but still have far to go before they have anything like customary winter stocks. This applies to most coal users except railroads and central power plants. In the tide market there has been an increase in the number of boats chartered for general trade.

An upward trend has set in at Baltimore, inquiry having increased encouragingly. Prices have stiffened to some extent. The export situation in the last few days has developed a better tone, and shipments for the first half of September exceed those of the entire month of August.

A hopeful feeling exists at Birmingham. Spot buying is somewhat better and contracts are being signed here and there. Inquiry for bunker and export coal is still light, though there is a fair tonnage moving regularly to Cuban points and some to South American interests. The railroads are taking more coal than for several weeks.

### Demand for Anthracite Growing

Hard coal is moving easily in the New York market. The call for stove coal has become so heavy that some believe it will be necessary to start an educational campaign to encourage the use of other sizes. Egg and chestnut also are moving rapidly and without any trouble. The demand for the last-named size shows a slight increase over last week. Independent quotations for the domestic coals are a little stronger, straight stove bringing as much as 50c. more than when taken with other sizes. Some of the independent operators are sold up for the next couple of weeks on the larger sizes. The steam sizes likewise are gaining strength.

Demand at Philadelphia from producers is holding its own, but with some difficulty, for with the exception of a strong demand for stove, all the other sizes are easy. Most operators find some difficulty in moving nut, pea remains almost stagnant and egg has not improved. Retailers feel that in order to make money they must advance prices in the face of increased mine prices. Steam coals are a trifle stronger, with better demand for buckwheat.

A tinge of chill in the air at Baltimore has increased orders for anthracite from householders. There is no rush, it is true, and stocks on hand are in most cases fairly liberal. The buyer, now that he knows that there is little chance of any early increase in retail prices, is not hurrying.

The situation at Buffalo is not much changed. When the weather turns threatening demand picks up, but a return of sunny days cuts it down again. Consumers depend on gas to a considerable extent. More small sizes of anthracite would be burned if a simple and effective blower device were obtainable.

Contracting for fourth-quarter coke at Connellsville is now completed, except as idle furnaces may go in, there being no immediate prospect of this. The contracting movement involved less tonnage than expected. The spot market remains quotable at \$3@ \$3.10. Spot foundry coke is easier in tone, but remains quotable at \$4@ \$4.50.

# Foreign Market And Export News

## Confidence Wanes in British Market; Upturn in Output

A less confident tone is strongly in evidence in the Welsh coal market, the volume of business done during the last week having perceptibly decreased. The apprehension of operators and miners regarding the effect of the Dawes plan on the coal industry in this country has spread to exporters, who are fearful of difficulty in selling coal against increasing German competition. The operators have resolutely declined to cut their prices any further, and many of them prefer to close their pits rather than to increase their losses by accepting lower figures. The lower grades of coal are keenly feeling the competition from the north of England, and, though Admiralty qualities are fairly easily disposed of, small coals are a problem. Inquiry from the Continent has decreased somewhat, and the home trade is quiet.

The Newcastle market on the whole seems to be getting steadily into greater difficulties. Prices are at their lowest ebb, and the pits are working short time where they are working at all. German, French and Belgian business is poor and trade with Italy has declined. Unemployment in Durham and Northumberland is getting to be a serious problem, and the miners take the view that reparation coal is responsible for all their troubles.

Production by British collieries during the week ended Sept. 6, a cable to *Coal Age* states, was 5,180,000 tons according to the official reports. This compares with 5,113,000 tons produced during the week ended Aug. 30.

Notice of termination of contracts has been given to 2,000 miners in Wales, the contention of the operators being that the workings are old and that production costs have been prohibitive. In Warwickshire 800 men have had seven day's notice to terminate contracts, the reason being that the operators cannot any longer carry their losses. In all cases efforts are being made to get the men employment at neighboring pits.

## French Household Coal Active; Industrial Grades Lag

There is no material change in the French coal market; the situation in industrial coals is still quiet, the stocks of no considerable importance; the house-coal trade conspicuously active.

The price schedule for October has not been established yet, but the opinion is that prices will remain unaltered, with, perhaps, the exception of dry and anthracite fuels.

Trading in British coals is almost at a standstill.

The Paris market continues to be bombarded with German tenders for the free sale of coal. The tonnage received so far, however, has been extremely small.

The agreements between the Ruhr industrialists and the M. I. C. U. M. have been renewed and will remain in force during the transitory period contemplated by the London protocol, comprised between the first and second verification dates of the Reparation Commission, that is, from Sept. 1 to Oct. 7.

Under the terms of these agreements the German mines have agreed to continue deliveries of coal and byproducts based on the programme established by the Reparation Commission. The prices will be fixed by mutual convention between the Reparation Commission and the German Government.

## Domestic Trade Strengthens Hampton Roads Market

Business at Hampton Roads shows some improvement, the domestic situation giving a boost to the trade. Tide-water business has not felt any real effect of the upturn in the domestic market, but the general outlook is pronounced better.

Domestic coal has strengthened from 50 to 75c. a ton, and there seems to be a seasonal increase in demand for all business, due to the increase in steel trade and other conditions. Foreign

business, however, showed no improvement, but the bunker trade has substantially increased. This has had a tendency to boost the market. Coast-wise movement is holding its own, with prospects of advancement soon.

## News Items From Field and Trade

### ALABAMA

A. F. Hilleke, manager of the coke department of the Semet-Solvay Co. and manager of the Solvay Process Company, has resigned. His assistant, J. H. White, has been appointed assistant to the vice-president of the Semet-Solvay Co. only, with jurisdiction over the Southern plants and those operated by the company elsewhere. Mr. Hilleke was district manager of the Semet-Solvay Co., having charge of all Southern plants, during the war. He supervised the construction of the North Birmingham plant of the Sloss-Sheffield Steel & Iron Co., where the Solvay process of coke manufacture is used. He was promoted to the Syracuse offices in charge of all coking plants in America five years ago.

The Pratt Fuel Corporation has made another addition to its active operations and coal land holdings by the purchase of the properties of the Nelson Coal Corporation for a consideration reported at approximately \$250,000. The lands of the Nelson corporation adjoin some of the holdings of the Pratt corporation recently acquired and carry one development on the Mary Lee seam at Red Star mines and consist of about 1,200 acres of coal-bearing lands on the Southern Ry. in Walker County. Frank Nelson, former president of the Nelson Coal Corporation and a well-known operator in the district for many years, becomes a director of the Pratt Fuel Corporation.

### COLORADO

John F. McDermott, formerly with the Leyden Coal Co., has been appointed assistant to W. F. Oakes, president of the Sunnyside Coal Mining Co., with mines at Strong, in Huerfano County. Mr. McDermott is spending a few days with R. T. Bell, the general superintendent, at the mines, to acquaint himself with the personnel, the operation, and particularly the preparation, as on him will devolve to a great extent the sale of Sunnyside coal. The company is just completing the installation of a Link-Belt Knox loading boom and a box-car feeder. The loading boom installation will deliver lump to open cars, or to the box-car loader, with a minimum of breakage.

H. H. Pinckney, of West Virginia, has succeeded J. C. Cheyney as vice-president and receiver of the Canon Reliance Coal Co. The Denver office has been closed and the sale of the coal put in the hands of the Colorado Agency Co. Mr. Pinckney makes his headquarters at Canon City. The company is oper-

ating only the Canon mine. The Reliance mine at Ojo is being worked by the Purity Coal Co., of Pueblo, of which John W. McGovern is president, Andrew McGovern, secretary and treasurer, and P. G. Cameron, vice-president and general manager.

Despite adverse conditions in the shape of very soft rock in the west side, work on the Moffat tunnel is being pushed by Hitchcock & Tinkler, the contractors. The face on the west side is in 4,400 ft. and on the east side 4,900 ft. These distances have reference to the narrow bores.

### ILLINOIS

Coal for the St. Louis city water works has been contracted for with a Marion mine for approximately \$2.75 per ton. Other mines in Franklin, Williamson and nearby counties have obtained contracts aggregating about \$400,000 from the City of St. Louis for the coming season.

The Old Ben Coal Corporation is about to reopen a number of its mines in Franklin County. Mine No. 12, commonly known as the East Mine, located near Christopher, will resume operations in a few days. Mine No. 10, also at Christopher, known as the Old North Mine, is being cleaned up and was to resume coal hoisting on Sept. 22. About six hundred men are employed at each of the two mines.

The mine of the Valier Coal Co. at Valier, owned by the Chicago, Burlington & Quincy R.R., has again resumed operations after six weeks' idleness. The mine has a daily average of approximately 6,000 tons and is one of the most modern and best equipped mines in the state.

James McSherry, for the past several years assistant superintendent of the Equitable Coal & Coke Co.'s three mines in southern Illinois, has resigned effective at once. His future plans have not yet been announced. He has been closely connected with the coal trade in the southern part of the state and is widely known. The Equitable concern is owned by the Crear-Clinch interests, of Chicago.

### INDIANA

The Indiana mining examinations for mine boss, fire boss and hoisting engineer will be held Oct. 11, beginning at 9 a.m. at Garfield high school in Terre Haute, according to announcement by John Stevely, deputy state mine inspector, of Clinton. Citizens who are 21 years old or over are eligible to take the examinations.

The Dixie Vein Coal Co., Indianapolis, has increased its capital from \$50,000 to \$100,000.

The Indiana Public Service Commission has granted permission to the Evansville, Indianapolis & Terre Haute Railroad Co. to construct six miles of switch track from Somerville to Francisco to open a new mining district. Under the plans the railroad would cross nine roads, but only six will be grade crossings. One of the grades is eliminated by a subway and the railroad will build a new highway which will eliminate two other crossings.

### KANSAS

Mine No. 6 of the Hamilton Coal & Mercantile Co., near Cherokee, has been reopened. It employs 200 men.

The Crowe Coal Co. has announced its intention to open another of its deep shaft mines in the Pittsburgh district within a few days, but has not yet determined which mine it shall be.

Representatives of the international executive board, United Mine Workers, who, on Sept. 13 completed a survey of conditions in District 14, found miners of the district employed 49 per cent of full time. The investigators, John O'Leary and W. D. Van Horn, recommended that national officers send a board of organizers into the district immediately to work for "100 per cent membership" in the organization.

### KENTUCKY

Within the next few days official notification of the sale of various of the properties of the Jewett, Bigelow & Brooks Company in Harlan, Perry, Bell and Pike counties, will be made by the receivers, E. S. Douglass and J. C. Richey. A court order to this effect has been given by Judge A. M. J. Cochran of the U. S. District Court of the Eastern district of Kentucky. It is understood that the date of sale for some ten of the mines has been set for the last week in October.

No successor to replace the late C. D. Boyd, as manager of the coal traffic bureau jointly operated by the Southern Appalachian, Hazard and Harlan coal operators' associations, will be named soon, due to the fact that none of these organizations has meetings scheduled for some time to come. In the meantime, Roy Carson, Mr. Boyd's assistant, is looking after the affairs of the office.

The Rogers Elkhorn Coal Co., which was recently incorporated, will develop 1,100 acres of coal land near Virgie, to a daily output of 500 to 700 tons.

## NEW MEXICO

The Rio Grande Eastern R.R. has requested authority of the Interstate Commerce Commission to construct a line between Santa Fe and Albuquerque, which it is said will enable the Hagen Coal Mines, Inc., to market 20 cars of bituminous daily; permit the Sloan Coal Co. to resume operations and enable the construction of a power plant which will furnish power for mines in that district.

## NEW YORK

Quarterly dividends of \$1.75 have been declared on the preferred stocks of Burns Brothers. The dividend on the ordinary preferred is payable Oct. 1 and that on the prior preferred Nov. 1.

The Rochester & Pittsburgh Coal & Iron Co., general sales department, 1 Broadway, New York City, announces that effective Sept. 15 John M. Nelson, formerly general sales agent of the company and more recently sales agent in Buffalo, was appointed assistant to J. Noble Snider, vice-president in charge of sales, with headquarters in the Prudential Building, Buffalo. Charles Braun, Jr., has been appointed sales agent in charge of the Buffalo sales organization.

## OHIO

A. C. Ingersoll, president of the Philadelphia & Cleveland Coal Co., in passing through Cincinnati said that the large wharves, dockage and unloading facilities which have cost more than a quarter of a million dollars and which will be one of the most up-to-date plants on the river would be opened for business by his company about Oct. 1. These will be used for transshipping coal down the river from the Logan County (W. Va.) mines. The head offices of the company will be moved from Cleveland to Cincinnati, new quarters having been taken in the Dixie Terminal Building.

The Brush Fork Coal Co., of Athens, has opened a sales office in the Atlas Building, Columbus, with H. H. Sisson in charge, with the title of sales manager. The mine is located at New Pittsburgh, in the Hocking Valley. The output is 600 tons daily.

Bellaire officials of the Cleveland & Western Coal Co. have received orders to place in operation three Belmont County mines owned by the concern. The mines, which are located at Stewartsville, Johnson and Powhattan, have been idle several months. About 750 men were given employment when the operations were started.

Lincoln Mine of the Lorain Coal & Dock Co., which was fired by an electrical wire several weeks ago, is now working 60 per cent, according to James Watson, chief inspector of mines of Ohio, following an inspection. The burning entries have been sealed and it is believed the flames will be extinguished soon. The Ohio mine rescue car Black Diamond was called in an effort to extinguish the fire.

Several conferences between operators' and miners' representatives in the Pomeroy field have been held at Pomeroy with a view of signing up an agreement containing concessions in the cost of dead work, similar to the Hocking Valley agreement made at Logan. The meetings were brought about upon invitation of the Pomeroy Chamber of Commerce. It is likely that an agreement will be reached soon.

Machines for loading coal in the mines made in Pittsburgh are being tried out in a number of the mines in the southern Ohio field, principally by the Essex Coal Co., in the Pomeroy field, and the Central West Coal & Lumber Co., in the Hocking Valley proper. The first-named concern has been using the machines for only a short time and would not venture an opinion as to costs of operation compared with hand loading, but the Central West Coal & Lumber Co. has been operating two machines for 90 days and has ordered a number of others. In case the machines prove successful costs may be reduced to a point where it will be possible to compete with other fields, principally the non-union fields of West Virginia and Kentucky.

Mine No. 25 of the New York Coal Co., located at Chauncey, started operations recently with about 200 men. The Luhrig operation of the same company, employing about as many men, also started operation last week.

## PENNSYLVANIA

Operations have been resumed at the colliery of the Tip Top Coal Co., Mountain Grove, after an idleness of several months. Many farmers from nearby valleys have been given employment at the plant.

Dr. Royal K. Meeker, State Secretary of Labor since Feb. 26, 1923, has presented his resignation to Governor Pinchot, it was announced at the Governor's office Sept. 11. The resignation becomes effective Oct. 15. Dr. Meeker, before taking the State office, had been chief of the scientific division of the International Labor Office of the League of Nations.

The H. C. Frick Coke Co., subsidiary of the United States Steel Corporation, have fired 125 additional ovens at its Phillips plant, making half of the 400 ovens at that place now making coke.

No. 15 colliery of the Lehigh & Wilkes-Barre Coal Co., one of the largest in the Plymouth district, will resume operations this week. Nearly 1,000 men were thrown out of work when the colliery was closed last Monday for repairs. Other operations of the Lehigh & Wilkes-Barre company are working with normal forces, officials state.

The quarterly dividend of the Westmoreland Coal Co. was cut in half when directors declared a dividend of 1 per cent, or 50c. a share, payable Oct. 1 to stockholders of record Sept. 25. In 1917 the Westmoreland company consolidated with the Penn Gas Coal Co. and Manor Gas Coal Co. The old Westmoreland Coal Co., incorporated in 1854, owned all the capital stock of the Penn Gas Coal Co., and with the latter company owned all the capital stock of Manor Gas Coal Co. The company now owns more than 15,700 acres of coal land situated in the Irwin Basin, Westmoreland County. It also owns and operates ten coal-producing mines, with a daily capacity of 15,000 tons. On June 19, 1923, directors declared a quarterly dividend of \$1 per share. The company prior to that time had been paying \$1.25 quarterly. This reduction followed the payment of a stock dividend of 33½ per cent in May, 1923.

### Town Site of Frances Mine, Franko, W. Va.

This newest operation of the Consolidated Fuel Co. is one of the most modern in regard to equipment in the Moundsville district. It comprises 1,671 acres underlaid with the Pittsburgh and Sewickley seams. The mining camp contains seventy houses in all constructed with a view to comfort, neatly painted and generously provided with ground area.

Courtesy Bertha-Consumers Co.

The Cascade Coal & Coke Co., an auxiliary of the Buffalo & Susquehanna Coal Co., put its mines and coke ovens at Sykesville in operation on Sept. 17, after a suspension of three months and will as soon as possible have the entire force of 500 men at work. Practically its entire output is taken by the Buffalo & Susquehanna furnace of Rogers, Brown & Co. in Buffalo.

Buck Mountain, the little anthracite mining town which furnished the smokeless coal which was burned on the Monitor when it engaged the Merrimac in one of the deciding naval battles of the Civil War, is practically a deserted village due to the fact that all fuel mined there now is taken to the Eckley and Drifton breakers of the Lehigh Valley Coal Co. One of the oldest collieries in the anthracite field is located at Buck Mountain.

The Lehigh & Wilkes-Barre Coal Co. has declared a dividend of \$3 on the common stock and a quarterly dividend of 1½ per cent on the preferred stock of the company.

## UTAH

Daniel Harrington, formerly supervising mining engineer with the U. S. Bureau of Mines, has opened an office in the Newhouse Building, Salt Lake City, where he will practice as a consulting mining engineer.

The Utah Supreme Court has ruled that the Utah Fuel Co. had the right to close the road up Miller Canyon in Carbon County. The court held that the coal company was justified on the ground that the road was on its own property. The action against the company was brought by a man who owns a store on the road.

The Sevier Valley Coal Co., Richfield, reports good progress in the development of its properties in Salina Canyon. The company expects to place considerable coal on the market in the near future. Machinery is being installed. It is the opinion of the officers of this company that coal mining will before long be one of the chief industries of this county.

L. F. Rains, president of the Carbon Fuel Co., Salt Lake City, acted as grand marshal in the twilight parade in Salt Lake City on Defense Day.

Utah mines produced 386,192 tons of coal during August compared with 359,527 tons in August of last year. In August, 1922, 498,285 tons were mined.

## WEST VIRGINIA

Although the Kanawha & Hocking Coal & Coke Co. won its suit in the court of Magistrate Hastings, at Montgomery, on Sept. 8 and by an agreement between counsel the one case tried was made to apply to 275 others involving unlawful detainer, nevertheless the company will not be able to get possession of its houses at Harewood, Oakland and Carbondale for a time, as the union has appealed the cases on behalf of the miners to the Circuit Court of Fayette County.

The Chaplin Collieries Co., having mine openings in the vicinity of the Osage plants of the Brady-Warner

Corporation, in the Scotts Run field of West Virginia, has followed the latter company's lead and posted notices that operations will be resumed on the basis of the 1917 wage scale. Although the Brady-Warner Coal Corporation announced a resumption a few weeks ago there has been no actual operation so far.

Output of coal in West Virginia during the fiscal year ending June 30, 1923, according to the annual report of the State Department of Mines of West Virginia, which has just been published, was 87,031,408 gross tons, as compared with 70,888,203 gross tons during the previous fiscal year, the increase amounting to 18.55 per cent. Production of coke amounted to 823,912 net tons as compared with only 145,156 tons during the fiscal year ending June 30, 1922. There were 1,110 companies reporting 1,402 operating mines. The total value of the coal and coke produced together with other interesting figures are given in the following table:

Total value of coal produced (87,031,408 gross tons)...	\$276,759,877.44
Value of coal used in operating (886,455 gross tons).....	2,818,926.90
Value of coal sold local trade and tenants (1,698,205 gross tons).....	5,400,291.90
Value of coal used in coke ovens (1,212,742 gross tons).....	3,856,519.56
Value of coal shipped from mines.....	261,504,139.08
Value of coal mined by small country mines (1,000,000 gross tons)...	3,180,000.00
Total.....	\$276,759,877.44
Value of coal sold (84,932,211 gross tons).....	\$270,084,430.98
Value of coke sold (823,912 net tons).....	5,882,731.68
Total.....	\$275,967,162.66
The increase in value compared with the previous year is as follows:	
Coal.....	\$92,094,061.23
Coke.....	4,856,317.50
Total increase in value.....	\$96,950,378.73
The coal produced was disposed of in the following manner:	
Produced by small country mines	Gross tons
—sold at mines.....	1,000,000
Used in operation of mines.....	886,455
Furnished local trade and tenants from commercial mines.....	1,698,205
Used in coke ovens.....	1,212,742
Shipped from mines.....	82,234,006
Total.....	87,031,408

The Algonquin Coal Co., operating at the head of Widemouth Creek near the Clarks Gap Tunnel, on the Virginian Ry., has been forced into bankruptcy. M. A. Kingsley, of the Kingsley Steamship Co., of New York, is the president and principal stockholder. John B. Rock, of Neal, W. Va., has been named as receiver of the company. It is believed that it will be possible to effect a reorganization of the affairs of the company by issuing long-term bonds in settlement of the claims of creditors.

## WASHINGTON, D. C.

In order to bring together into one administrative unit the related work of the sections of coal and of oil and gas in the division of geology, the old fuel section of the U. S. Geological Survey has been revived by combining the separated sections. W. Taylor Thom, Jr., has been placed in charge of the section on geology of fuels thus formed, with the title of geologist in charge.

## CANADA

Nearly all of the bituminous mines in the Cape Breton area have resumed normal activities. Although no official announcements have been made by the various companies including the Dominion Coal Co., subsidiary of the British Empire Steel Corporation, it is understood the mines are working to fill railway orders, which have been heavy since early in the spring.

The annual financial statement of the Blue Diamond Coal Co., operating in Alberta, for the fiscal year ending June 30 shows a loss from operations amounting to \$75,144, as compared with a profit of \$157,343 in the preceding year. The liabilities for taxes, royalties, interest, etc., brought the total loss up to \$124,950 as compared with a net profit of \$40,732 a year ago.

The city of Montreal has let a contract for 4,500 tons of American anthracite to the Ogdensburg Coal & Towing Co. at \$12.85 per ton. The fact that in asking for tenders American anthracite was specified to the exclusion of importations from Great Britain, aroused a good deal of criticism. L. O. Pion, city purchasing agent, when asked for an explanation, said: "The only reason is that we know of old that American anthracite has done the work required and we do not feel that we should begin experimenting. Until we can be shown that some other coal can do the work for the price we shall have to abide by the old standard."

The Chu Chua Coal Mining Co., with holdings near the City of Kamloops, B. C., is unwatering its workings and expects to be able to resume production this winter. Development is in progress on the property of the Wigham Collieries, which also is in the Kamloops field.

George Watkin Evans, a recognized authority on coal mining, has been retained to examine and submit a special report on the No. 8 mine, Cumberland Canadian Collieries (D), Ltd. This mine was opened, but not extensively exploited and was closed down shortly before the war. Recently a start was made toward unwatering it and Mr. Evans now has been asked to furnish the management with independent advice as to the economic possibilities of the enterprise.

After being shut down for nine weeks after the explosion of July 1 the shaft of the Allan mine of the British Empire Steel Corporation went into operation Sept. 15. Mining has been resumed from the 500 ft. level and Manager Blue expects to raise 600 tons of coal daily and gradually to increase the amount.

Efforts to force the Sydney Mines Council to resign *en bloc* have failed. Representatives of the local Communist organization in the United Mine Workers' ranks sought to force the entire council to hand over the administration of the mining town to the Communist group. This action was taken because the miners charged that the Council was not sufficiently active against the Dominion Coal Co. and the parent concern, the British Empire Steel Corporation.

## Traffic

### Ohio to Test Rate Decisions of Illinois and Indiana Courts

Attorney General Charles C. Crabbe, of Ohio, will take steps immediately to investigate the decisions of Indiana and Illinois courts governing the interstate freight rates on coal in those states, as requested by Governor Donahey in a message to the Attorney General. Mr. Crabbe was unprepared to state whether the Indiana and Illinois opinions would affect the situation in Ohio, but declared that he would give the matter immediate attention and carry it before the Utilities Commission and the Interstate Commerce Commission if necessary.

In a letter to Attorney General Crabbe, the Governor directed the latter to bring test cases immediately in Ohio courts to determine whether the Ohio Public Utilities Commission has authority to fix interstate freight rates on coal shipments and if so decreed, to have the Utilities Commission take such action.

### Indiana Divides on Coal Rates From West Virginia

Approval of plans for an aggressive fight against the petition of the Indiana State Chamber of Commerce asking lower coal rates from West Virginia to Indiana points, was given Wednesday, Sept. 17, by the directors of the Terre Haute Chamber of Commerce. Immediate steps are contemplated to organize all agencies opposing the petition into one concerted effort directed by the Traffic department of the Chamber. This will include the participation of the towns of Sullivan, Bicknell, Clinton, Princeton, Oakland City, Petersburg, Boonville and Linton with the co-operation of the Indiana Bituminous Coal Operators' Association.

The proposed petition originated with influences brought to bear upon the state chamber from the northern section of the state, which consumes vast quantities of coal but produces none. At the time the matter was under consideration the Terre Haute chamber interceded against the filing of such a petition on the ground that it would put an additional handicap and discrimination upon the Indiana coal fields.

### New Lehigh Valley Coke Rates Approved in New York

The New York Public Service Commission has approved new rates effective Sept. 8, 1924, on the Lehigh Valley R.R. for coke (including coke breeze, coke dust and coke screenings), carload minimum weight to open cars 30,000 lb. (except that when cars are loaded to full visible or cubical capacity actual weight will apply, but not less than 35,000 lb.), in box or stock cars 40,000 lb. (rates per net ton) from Harriet to these stations on its lines: East Waverly, Lockwood, and Van Etten Junction, \$2.27; Van Etten to Newfield inclusive, \$2.14; Ithaca to MacDougal inclusive, \$2.02; Cayuta to Burdette, inclusive, \$2.14; Hector to Yale, inclusive, \$2.02; Geneva, \$1.89;

Waterloo and Seneca Falls, \$2.02; Preemption to Naples, inclusive, \$2.14; Oaks Corners, Phelps and Clifton Springs, \$1.89; Manchester to Mendon, inclusive, Rochester Junction to Rochester inclusive, and Rush to Holmes, inclusive, \$1.51; Stafford and Batavia to Longwood Junction, \$1.39; Depew, Niagara Junction and Williamsville, \$1.01; North Tonawanda, 72c.; Niagara Falls and Suspension Bridge, \$1.01; Elmira to Cortland, inclusive, Hanna to Owasco Lake, inclusive, Brick Church to North Fair Haven, inclusive, and McKinney to Half Acre, inclusive, \$2.27; Auburn, Throop and Weedsport, \$2.02.

### Second Hearing Soon on Rate From Nelsonville to Columbus

The second hearing on the complaint brought by the Ohio Collieries Co., attacking the rate on the Hocking Valley Ry. from the Nelsonville field to Columbus, will be held before the Ohio Utilities Commission soon. The rate of \$1.23 is attacked because of alleged discrimination, as the rate into Columbus from the Pomeroy field is the same. The first hearing was held in August, when the Ohio Collieries Co. presented its side of the controversy. The next hearing will be the inning of the Hocking Valley Ry. Co.

## Obituary

**Samuel A. Rinn**, well-known coal operator and business man of Jefferson County, Pennsylvania, died at his home in Punxsutawney on Sept. 15, after an extended illness. He was born in 1860 and began coal mining when a young man. He was long in the employ of the Rochester & Pittsburgh Coal & Iron Co., for ten years having charge of the company's Adrian, Eleanor and Helvetia mines. He was an organizer of several banks in neighboring towns and actively connected with many other public enterprises. In 1892 his private coal interests had become so extensive that he resigned his position with the Rochester & Pittsburgh Co. to attend to them. He was president of the Punxsutawney National Bank and of the Central Pennsylvania Bankers' Association.

## Coming Meetings

**National Safety Council.** Thirteenth annual safety congress Sept. 29 to Oct. 3, Louisville, Ky. Managing director and secretary, W. H. Cameron, 168 No. Michigan Ave., Chicago, Ill.

**Alabama Mining Institute.** Annual meeting, Oct. 7, Hotel Hillman, Birmingham, Ala. Secretary, James L. Davidson, American Trust & Savings Bank Bldg., Birmingham, Ala.

**Illinois Coal Operators' Association.** Annual meeting, Oct. 7, Chicago, Ill. Secretary, C. E. McLaughlin, Fisher Bldg., Chicago, Ill.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

**American Gas Association.** Sixth annual convention and exhibition, Steel Pier, Atlantic City, N. J., Oct. 13-17. Secretary, Alexander Forward, 342 Madison Ave., New York City.

**Canadian Institute of Mining and Metallurgy.** Sixth annual Western Meeting, Oct. 16-18, Blairmore, Alta., Can. Secretary, Moses Johnson, Blairmore, Alta., Can.

**Coal Mining Institute of America.** Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 909 Chamber of Commerce Bldg., Pittsburgh, Pa.

## New Equipment

### Will Illuminated Spectacles Replace Cap Lamp?

As is well appreciated adequate mine illumination is one of the most vital problems with which the coal operator must deal today. Some coal producers light their mines electrically from the surface to the working face. Others are content with furnishing electric cap lamps to their men. Such lamps have the advantages that they are entirely self-contained, portable, explosion-proof units, unaffected by the mine atmosphere or the velocity of air cur-

### Heavy Illuminated Spectacles

Current may be supplied by an ordinary storage battery carried on the belt. The eyes are protected from direct light.

rents. To a large degree also they project the light to the point at which the wearer is looking.

Medical practitioners, surgeons, dentists and the like have long employed a head lamp somewhat similar to that used by the miner for throwing a concentrated beam of light to places requiring brilliant illumination. An improved lamp of this kind has been devised by Alford Pimenta of New York City and patented in the United States and England. It is shown in the accompanying illustrations.

This device which might be considered rather as a pair of illuminated spectacles than as a lamp is made in two sizes. The smaller of these will probably prove more applicable to the mines than the larger as it gives a wider field of vision. Ordinary small light bulbs such as are used in hand flash lights are employed in this device and the direction in which the light is projected is adjustable to suit the individual wearer.

The parabolic reflectors with which this device is fitted project the light from each lamp in a powerful ray for as much as 300 ft. from the wearer in the direction in which his gaze is directed. No light from the lamps can enter the eye and as a result the strain upon it is small. Furthermore the eye

#### Light Spectacle Type of Lamp

When lamps are protected by lenses the light may be concentrated on any point desired.

of the wearer is protected from dust and flying fragments of coal or rock while the light bulbs are protected by thick lenses. The entire device weighs but a few ounces and may be supplied with current from a battery carried on the belt in the ordinary manner. Thus far it does not have any of the devices for breaking the current should the bulb be broken.

#### Can Set Electric Hoist on Timber Floor or Column

A small, compact, powerful, little electric hoist has recently been developed by the Sullivan Machinery Co., 122 South Michigan Ave., Chicago. The com-

plete hoist can be fitted with a 6½-hp. motor and made portable for easy transfer from one place to another. The drum is equipped with extra-heavy brakes. The complete hoist weighs only 480 lb. and has a capacity of 2,000 lb. dead load lifted vertically at the rate of 110 ft. per minute. The base of the hoist is arranged so that it can be mounted on a cross-bar or column, or be bolted to timbers, girders or floor.

The complete unit shown in the illustration is equipped with a 230-volt direct-current motor supported in one end of the frame. This motor supplies power through shafts on ball and roller bearings, to speed reduction gears inside the drum. The single-drum hoist holds 500 ft. of ⅝-in. rope. Double-

drum hoists may also be obtained having the same general characteristics. The starting box furnished with each hoist is moistureproof and is so constructed that it can easily be hung from a post by means of a spike.

#### Turbo-Blower Delivers Air to Boilers Without Loss

A new high-efficiency turbo-undergrate blower has just been added to the general line of blowers manufactured by the Buffalo Forge Co., Buffalo, N. Y.

#### Turbo-Undergrate Blower

This complete unit is equipped with heavy anti-friction bearings larger than actually required. The blades are designed so as to practically eliminate any backward flow of air.

This device has a six-blade propeller wheel made of aluminum and is provided with a cast-iron housing. When driven at 4,000 r.p.m. the 16-in. propeller wheel will deliver 6,000 cu.ft. of air per minute.

It is claimed that the blades on the fan are designed so as to operate at unusually high efficiency. Where the peripheral speed is lowest, at the hub or center, the pitch of the blades is greatest and is gradually reduced at the tip where the speed is highest. It is also claimed by this design the pressure conditions are more nearly equalized and the backward flow of air near the center of the rotor is entirely eliminated.

A specially designed turbine has been developed for this blower. It has a

wheel made of monel metal and is mounted in ball bearings. When used with undergrate stokers the complete unit may be connected with a pressure-regulating valve so that the volume of air delivered into the ashpit will vary inversely as the steam pressure.

#### Single-Drum Electric Hoist

This completely inclosed outfit is serviceable in damp places. The motor is inclosed and mounted in the end of the drum which it drives through anti-friction bearings.

#### Paper Pulley with Improved Double-Locking Hub

A new line of paper pulleys having a double-locking hub has just been placed on the market by the Best Pulley Manufacturing Co., 400 Talcott Avenue, St. Louis. The hub of these pulleys has three sets of winged locking grips which prevent the hub from becoming loose even when the pulley is strained under load or suddenly reversed. These ribs are part of the hub and extend through the whole width of the pulley so that when the hub is pressed into position they become an integral part of the pulley itself. Over 2,500 stock sizes of this improved pulley are now being manufactured.

#### Paper Pulleys with Locked-In Hubs

A specially designed hub is forced into the center of the pulley so that the paper and hub lock closely together and cannot come loose.

## Paying for His Keep

**A**N ELECTRICAL-MECHANICAL engineer employed by a coal-mining company in Illinois said the other day that a few years ago he decided that each month he would try to do something special for his company which would more than pay for his salary.

The success that has attended his efforts shows that there is much to be done in improving conditions at nearly every coal mine. This man's greatest improvements were in realizing savings in operating costs. Needless to say he found himself often in a position where he had to change old methods for new, and consequently had to overcome the inertia of that kind of people who are satisfied to do things as grandfather always did them.

One might be surprised to know that this man was not working for a backward, inefficiently operated company. On the contrary he was employed by a relatively progressive firm, yet he is one of few in that company who want short cuts. He says that it is an easy matter to effect savings in these days when many new and more efficient methods are being introduced to the mining field.

Opportunities for improvements exist at all mines and the day is rapidly coming when mine officials will realize that more engineers of this type will be the profit makers of the future. "One new saving every month" would be a good motto for every mining engineer.

## Square Company Shooting

**C**OMPANY shooting can obviate many difficulties encountered in coal mining. It has been proved conclusively that where company men drill and shoot the factor of safety is raised and the proportion of screenings is lowered. More than one operator in a solidly unionized field has yearned to take over the shooting in his properties and has envied the non-union man who could readily do it without danger of drawing down upon his head the wrath of a powerful labor organization with a bludgeon in one hand and a contract in the other. However, operators who are free to assume complete control of the use of explosives in their mines, as some are doing in Utah lately, need to be temperate in the differentials they fix under contract rates.

It would seem that a differential as high as 30 per cent is excessive and the fixing of it on the theory that it is merely to compensate the company for its share of the expense of mining is deceptive. If it was admitted freely that the level of wages was being reduced in the process and both parties clearly understood this, then the differential should not be questioned. But reducing contract mining rates nearly if not entirely one-third on any other basis is likely to engender bitterness between employer and employee.

Such bitterness is not productive of good for anybody directly or indirectly concerned—except the United Mine Workers of America. That organization would be pleased indeed if most of the operators of Utah, for instance, were to stir up feelings of great discontent among their men. It would then be a most desirable state within which to conduct a vigorous organization campaign and everybody knows the United Mine Workers needs a few more fertile states in which to plant the seed of organization. The losses of territory already have been heavy enough for Mr. Lewis and his associates.

So we feel like cautioning Utah operators who tell their men that contract rates must be reduced one-third in order that the company be barely compensated for furnishing powder, setting shots and firing them. Few farseeing operators there or anywhere else would adopt such a course. Most of them are too honest with their men for that. There are a great many advantages to company shooting and we hope more Western mining companies adopt the practice—but they should play square with their men.

## Coking by Steam

**T**HE quest for a satisfactory method of low-temperature coal distillation has in the past proved somewhat unsatisfactory. High-temperature coking has been brought to a fair degree of perfection, but when an attempt has been made to coke the coal at a low temperature, obstacles have promptly been encountered. Chief of these difficulties has been the excellent insulating qualities of the material treated.

It is probable that the resistance to heat transfer possessed by many substances such as asbestos, magnesia, feathers, felt, fur, wool, wood and the like results from the large number of small air spaces that the material contains. These may be either cellular or interstitial—that is, air may be entrapped within the cells of the material itself or it may exist only between the fibers or granules of the insulating substance. In the first instance the air might be considered as forming an integral and inseparable part of the material; in the second it merely fills the voids between particles.

Air-filled voids in the oven charges have so delayed heat transference that various agitating devices have been employed. Few have proved themselves commercially important.

Within the past few years a medium has been undergoing development that in the future may play an important rôle in the low-temperature distillation of coal. This is highly superheated steam. Today steam is being superheated to temperatures which only a few years ago were considered both impossible and dangerous. No particular difficulty is encountered in imparting to water vapor a temperature of, say, 1,000 to 1,200 deg. F.

Forcing steam of this temperature through a mass of

finely crushed coal in a coke oven displaces the interstitial air and quickly brings the mass to a coking temperature. Experiments performed on coke ovens of this kind show that coke can be made by this means in approximately 2½ hours whereas a much longer period is required for coking by the usual method of heating the side walls. Gas and other byproducts given off from coal coked by steam are readily separable from it by condensation and scrubbing.

As an industry the manufacture of high-quality smokeless fuels from low-quality smoky coals is yet in its infancy. There is little doubt, however, that it is destined to assume an increasing commercial importance as the years go by. Using a superheated vapor to carry the heat necessary for coking to practically all portions of the charge of coal in the oven would seem to open a wide range of possibilities in this direction.

### Mining Engineer Architects

OUR AMERICAN mining villages bear eloquent testimony to the work of the mining-engineer architect, and it is not testimony of which we can be proud. Such a general utility man as the mining engineer can never hope to be an architect, and the company in the Campine, of Belgium, which decided to employ specialized designing talent is to be congratulated on its decision. The town, illustrations of which appeared in these pages recently, bears witness to the advantage of letting the work be done by those who have devoted their lives to that study.

Operators of coal mines should be as ready to seek architectural design and supervision as railroad companies are to employ chefs to prescribe the menus on their dining cars and to supervise the service. Even if a mining engineer shows a flair for architecture, his employers are so doubtful of his ability in that direction that he finds himself unsupported and is driven to follow old-fashioned and unsightly designs. The architect of experience would find his judgment less questioned and would be able accordingly to construct a presentable village. After all, mining towns are for human habitation, and men demand something besides mere utilitarian comforts. They are appreciative of beauty or can acquire that appreciation.

### Indictments

OTHERS than coal men can be indicted—the household, for instance, with a furnace and coal cellar idle through the summer months. Radiators and piping also idle—another economic waste. The consumer's equipment is not 100 per cent efficient. It is working barely 50 per cent of the time. With such a condition of affairs in his home how can the consumer be critical of the coal industry with its 66 per cent efficiency?

We wonder whether the radiators might not during the extreme heat deliver a genial coolness to our habitations and make life bearable. Why should the radiator be restricted to delivering heat when it might be filled with cold air and thus continue to be a source of comfort? The janitor, who in summer months is relatively idle, could have work the year round instead of half the year. In suburban regions he spends his time gardening but in the city he is dismissed unless he has a group of apartments to keep swept and garnished.

Our forefathers shivered in the winter's cold. It

seemed perfectly natural to them. We swelter in the summer. It seems quite the regular order to us. But need it be so? Why not have comfort the year round? The ice industry it is true has aided in making life endurable, but, like the grate fire, it is a partial remedy. We should keep more than our comestibles at a proper temperature.

### Domestic Storage Aids Industrial

SCREENING shortages quite frequently occur during the summer; the price increases accordingly and in consequence the industrial buyer is not encouraged to do his purchasing early. The operator producing a domestic coal cannot afford to crush it so as to satisfy the manufacturer or public utility or to sell it at screening price. Consequently he produces only as much coal of that size as the demand for domestic coal provides.

The only coal that usually can be obtained in unlimited quantity and at the lowest price during the summer is the run of mine produced at those low-volatile mines which do not supply the domestic market. This coal is of such high quality that the purchaser can afford to pay, and is willing to pay, even in years like this, approximately at least what it costs to produce, or in any event he is more ready to do so than when he is buying the screenings at a high-volatile plant.

Consequently unless the buying of the domestic consumer can be hastened so as to extend into the summer the industrial purchases of high-volatile screenings can hardly be greatly speeded, for the latter depend on the former.

Of course there are two slightly different interests in the coal regions. The high-volatile producer, though he objects to the domestic consumer being so opposed to fine coal that he will buy lump coal to break it down with a hammer to fit his stove, finds, however, that in that objection lies his sole opportunity to sell his coal at a profitable price. If the consumer were willing to burn slack, he also could get his coal from the smokeless-coal mines which cannot make lump coal, and the high-volatile producer would be deprived of the most profitable part of his market.

So the demand for the greater use of slack may become ultimately in a sense sectional. The high-volatile producer wants to sell all the slack he produces, and he does not like to be held in any way at fault for degradation of his coal on the way to the market, but at the same time the willingness of the consumer to pay a higher price for a lump coal is the only thing that keeps him out of the bankruptcy court. Consequently if the use of fine coal becomes at all general he will cease to be keen to educate the public away from the larger sizes, for in doing so he may lose his domestic as well as his industrial market.

The high-volatile man always is in a quandary. Either there are not enough buyers of large coal or not enough of small. He wants them both; the purchasers of lump because they are willing to pay him a profit and the purchasers of slack because they prevent him from showing a total loss on that commodity, but if the users of slack call on him heavily in the summer when the domestic consumer is indifferent, he is obliged to turn a deaf ear to them because slack is to him only a byproduct. He cannot afford to make this unprofitable size in order to help the buying-early movement so long as the lump consumer refrains from entering the market.

Street Scene, Kramer.

## Kramer Mine Houses Its Stay-at-Home Employees

Only One Employee in Every Four Lives at Mine—Each Man Requires 4.4 Rooms—Two-Story Houses Accommodate Two Men Each at Cost 32.5 per Cent Less Than Bungalow Type

BY ALPHONSE F. BROSKY  
Assistant Editor, *Coal Age*,  
Pittsburgh, Pa.

**A**UTOMOBILES, good roads and a general rise in the standard of living are creating new housing problems for the American mine owner. Workers who desire a certain degree of independence and the advantages inherent in living in a residential and business atmosphere are willing to pay bigger rents and travel to and from work by auto a distance sometimes as great as 10 miles. This releases the mine owner from the obligation of housing many of his employees. Pennsylvania bituminous miners in this respect are falling in line behind those of Illinois, the procession being led by the anthracite workers.

But with the rise in the standard of living the mine owner is obliged to assume the burden of providing more commodious quarters for those of his men who still choose to reside in the mining towns. He must also give them some of the conveniences found in the larger municipalities and cities. These factors influenced the plans adopted by the Northwestern Mining & Exchange Co. for building a mining town at its new Kramer operation, which was opened in 1920.

The new Kramer shaft mine lies in Jefferson County, Pennsylvania, 10 miles south of Dubois. It is designed for a maximum production of 4,000 tons of coal in 8 hours. About 800 men, including the necessary supernumeraries to fill the places of absentees, eventually will

be needed for the operation of this mine. At the present time approximately 300 men are employed in double-shift entry work and on the surface. Early this autumn room work will be started; when this is begun about 500 men will be employed. This number will be sufficient to produce 2,500 tons of coal each working day. As this rate of output, after it once has been attained, will not be exceeded for several years, the company has built a town sufficient to house only those of the employees required to produce this tonnage who do not choose to live in nearby communities.

### ONLY A QUARTER OF EMPLOYEES REQUIRE HOUSING

Observation of the habits and proclivities of miners residing in the field surrounding Dubois, as well as past experience, enabled the Northwestern Mining & Exchange Co. to estimate the necessary initial capacity and the ultimate size of the town of Kramer. Two salient facts thus were established: First, only 25 per cent of the men employed need be housed in company-owned dwellings; second, only 4.4 rooms are required on the average to house each working man and his kin residing in the town. Accordingly, in order to house 125 of the 500 workmen that will be needed to produce 2,500 tons of coal daily 100 houses having a total of 550 rooms have been erected. Practically all these are occupied by company men. Information of this kind is of value only to those contemplating

NOTE—The owners of Kramer mine prefer to erect the two-story six-room houses shown in the headpiece because they are cheaper than dwellings of the bungalow variety. Note how the houses are set in pairs for protection in case of fire.

Front and Side Elevations and a Few Constructional Details

It will be noted that the houses are plain yet reasonably substantial. There are no ornate trimmings, the structure being designed for utility rather than beauty.

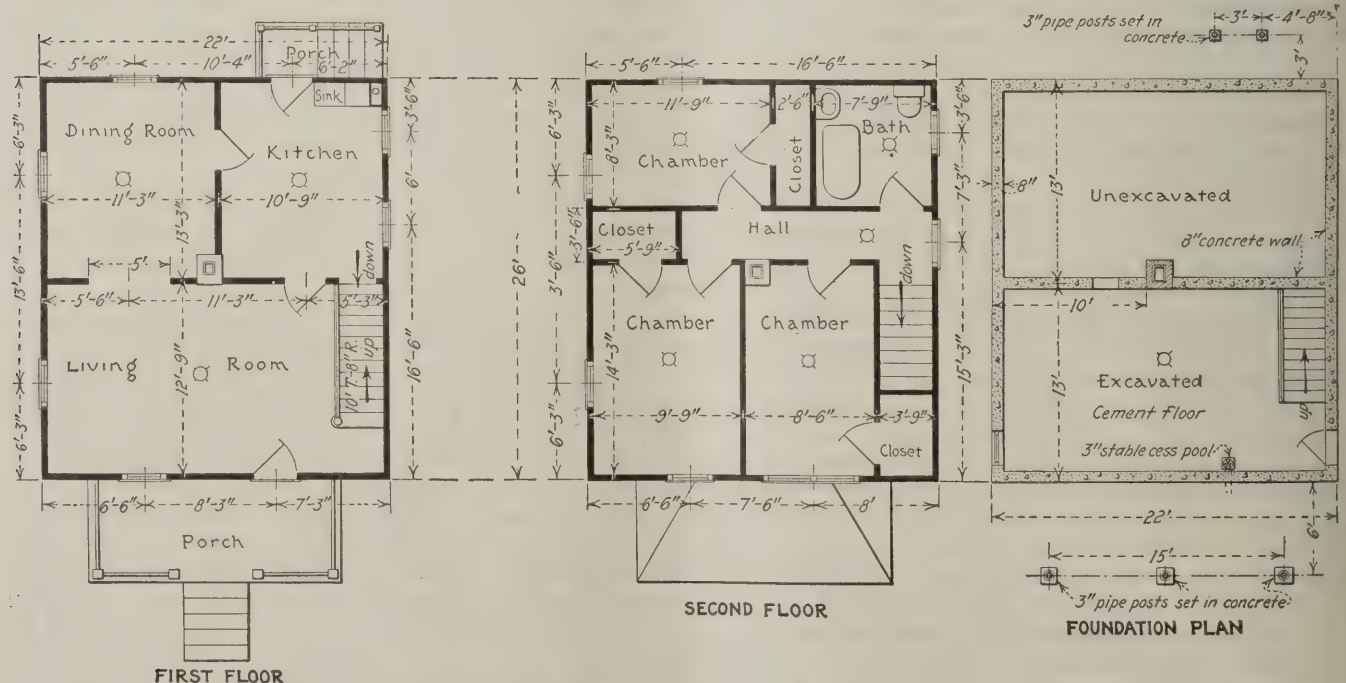

the erection of a town in a mining district connected by satisfactory traveling facilities with established communities.

Of the one hundred houses already built, ten are two-story structures containing seven rooms each. These are intended for occupancy by the bosses and the office force. Fifty two-story houses have six rooms each; this type has proved highly satisfactory, as will be explained later. The remaining forty houses are of the bungalow type, twenty having five rooms and the other twenty having four rooms each.

Before the daily output can reach 3,500 to 4,000 tons, at least 100 more houses will have to be constructed. The company has about decided to make these dwellings two stories high and of the six-room type, conforming in construction to the six-room houses already erected. This type of house probably will be adopted as a

standard, chiefly because it will accommodate an average of two workmen as against one in the case of the smaller dwellings of the bungalow type. The reason for this is obvious when it is considered that the bigger house contains one more bedroom than the bungalow and that the rooms are larger. Married couples with no children may take in as many as four boarders, families containing two or three children may accommodate one or two boarders and large families may occupy an entire house. On the average, each six-room house should shelter two workmen.

The five-room bungalow is exactly like the four-room type, except for the addition of a small room adjoining the kitchen. In the four-room plan a single room serves as both kitchen and dining room. In the five-room type the additional room can be used either as a kitchen or as a storeroom. Thus, though the

Floor and Cellar Plans for Two-Story Houses

Here again utility is the keynote of design. A large living room together with a good sized dining-room and a kitchen of almost equal size make up the first floor. Three chambers and a bath, together with ample closets are found on the second floor. Half cellars requiring the least excavation are placed under these houses.

Front and Side Elevations, Also a Few Details of the Bungalows

The advantage of the bungalow lies not in its cost but rather in its convenience. So far as the coal company is concerned, however, it cannot allow this consideration to outweigh the housing utility of the two-story dwelling.

larger house is more convenient, it offers no more spacious accommodations than the four-room bungalow. People living in either type are cramped for space and dislike the idea of taking in boarders. The six-room house possesses a further marked advantage in that only three rooms per workman are required as against 4.4 rooms in the bungalow.

#### SIX-ROOM TWO-STORY HOUSES BEST INVESTMENT

As practically the same quantity of material and labor enters into the construction of the roof and foundation in the six-room house as in the four- or five-room bungalow, the cost differential between it and the six-room structure represents only the additional material and labor necessary to the construction between these two extremities. Excavation, foundation and roof construction are items that make up a goodly portion of the total cost. Inasmuch as the cost of the six-room house is only 35 per cent greater than that of the five-room bungalow, the expense of housing a workman in the former is 32.5 per cent less than in the latter. Of course, this calculation is based on the assumption that the occupants of the houses will take in boarders whenever circumstances permit them to do so.

As the accompanying plans and elevations of the several types of houses in the town of Kramer give the layouts, proportions and many of the details of construction, little comment other than a few general remarks is necessary here. The walls are constructed

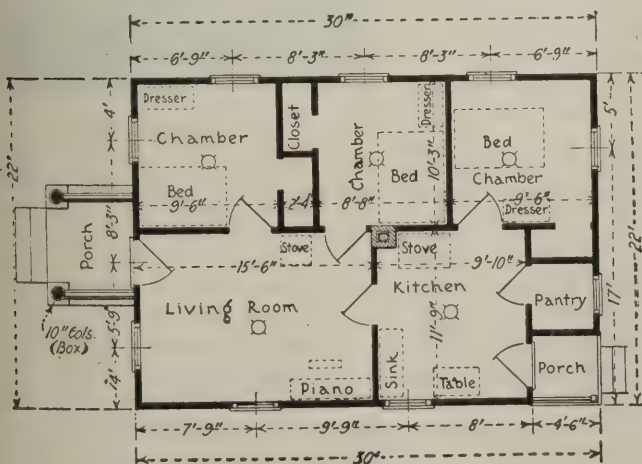

of 2x4-in. studding, lathed and plastered on the inside and drop-sided on the outside. Floors are built of tongued-and-grooved flooring resting on 2x8-in. joists spaced on 16-in. centers. Chimneys are constructed of a single course of bricks inside which is placed 1-in. flue lining tile, the clear opening being 8x12-in. The pier on which the chimney rests forms a part of the center wall of the foundation.

Each window sash contains one large pane of glass in place of four, this latter construction being frequently followed in building miners' dwellings. The large glass is a great convenience to the housewife in cleaning windows. The upper and lower sashes are provided with counterbalancing weights. This is a departure from general practice in this region. It eliminates the inconvenience and breakage caused by falling sashes. These two details might well be incorporated in all miners' houses. Roofs are covered with extra-heavy composition roofing paper.

Foundation and cellar walls are of concrete 8 in. thick. Each cellar is excavated under only half the house area, though the foundation wall extends completely around the building. The half-cellar requires the pouring of a center wall extending from side wall to side wall. When a house is built on sloping ground, the cellar is located under that portion of it where the ground is the lowest, so that the excavation is kept to a minimum. The cellar floors are concreted. Entrance into the basement is gained through an outside door in all except the seven-room houses, which are provided with an inside stairway for this purpose.

All foundation walls were poured with a concrete mixture, the proportions of which were 1:3:5. The coarse aggregate used was  $\frac{3}{4}$ -in. crushed limestone, sometimes termed  $\frac{3}{4}$ -in. screenings. This comparatively small and uniform material facilitates puddling in narrow forms and is disseminated uniformly throughout the wall mass, whereas a heavy aggregate—a 2-in. size was tried—sinks to the bottom.

The utility of the cellars was increased by providing each with a chimney flue so that a small stove might be set up for heating either the basement itself or water for washing. As each cellar is provided with a water faucet and a 3-in. stable cesspool with a bell trap, it can be made to serve either as a laundry or as a place where the miner may change his clothes. Though all houses are provided with running water, only the seven-room dwellings have bathrooms and 30-gallon range boilers or hot-water heaters. Every kitchen is provided with a sink.

Bungalow Floor Plan

The four-room bungalow is laid out similar to the five-room type here shown, the difference between the two being only slight.

### A Bungalow Street

If he has no family or only a small one the miner frequently prefers the bungalow type of house. Many of them, however, prefer a larger dwelling so that they can keep boarders. Kramer is a new town; consequently streets have not yet been graded.

Water for drinking, washing and fire protection comes from a well 220 ft. deep, located near the auxiliary hoisting shaft. Thence it is forced against a head of 240 ft. by a pump having a capacity of 40 gallons per minute to a 20,000-gallon cypress storage tank. The intake pipe to the tank is 3 in. in diameter, and the discharge 4 in. The effective head at points in the town varies from 100 to 180 ft.

It has been observed by officials of the company that the average family living in houses without bathrooms will use about 50 gallons of water daily. On this basis 20,000 gallons of water is sufficient for one day's supply for 250 families (the number that some day must be accommodated in the town) as well as for a proposed bathhouse, the shops and other buildings. By pumping continuously, the tank can be completely filled in 8½ hours.

In case the water-storage tank, for any reason, must be emptied, the pump can be so bypassed as to discharge directly into the 3-in. cast-iron main. This water line is fitted with bell-and-spigot joints caulked with leadite. Twelve fire hydrants are installed throughout the town and so disposed as to afford fire protection to every house in it. These hydrants are of the anti-freezing type—that is, so designed that the water column automatically drains. Loose stone is buried at the base of each hydrant to receive the drain water.

As an added protection against the spread of fire,

houses located on adjoining lots are set in twos with an extensive open space between each pair. Lots have 50-ft. fronts and are 100 ft. deep. Streets are 40 ft. wide with a 20-ft. alley midway between each two that are parallel. Front building lines are 20 ft. back from the street lines. A plan that has worked out to advantage in this village is that of separating the town into two sections, one for people of American birth and the other for foreigners.

From the water mains a 4-in. tap line is run to each pair of houses. On each of these tap lines close to the main is inserted a corporation cock for shutting off the water supply to the houses served, in the event of a leaky pipe or other accident. Adjoining the corporation cock an 18-in. lead gooseneck is inserted in the tap line. This gives flexibility to the connections and prevents a break, should either the tap line or the main settle below the levels at which they were first laid. Two house lines, of course, are connected to each tap line, one to each of a pair of houses. In each of these branch lines is placed a stop-and-waste cock for drainage purposes.

The town has been built on a flat-topped hill covered with loose surface material of a broken and sandy nature. This gives natural surface drainage.

Two complete sewer systems have been installed. One is of the surface or open type and handles waste water from the four-, five- and six-room houses. It provides a quick run-off for surface water after a heavy rain. The other is of the sanitary or closed type, intended for handling waste water and fecal matter coming from the ten houses equipped with bathrooms. Each system, of course, is independent of the other.

The surface-sewer system, which cares for ninety of the one hundred houses, thus far constructed, is laid

### Kramer Water Tower

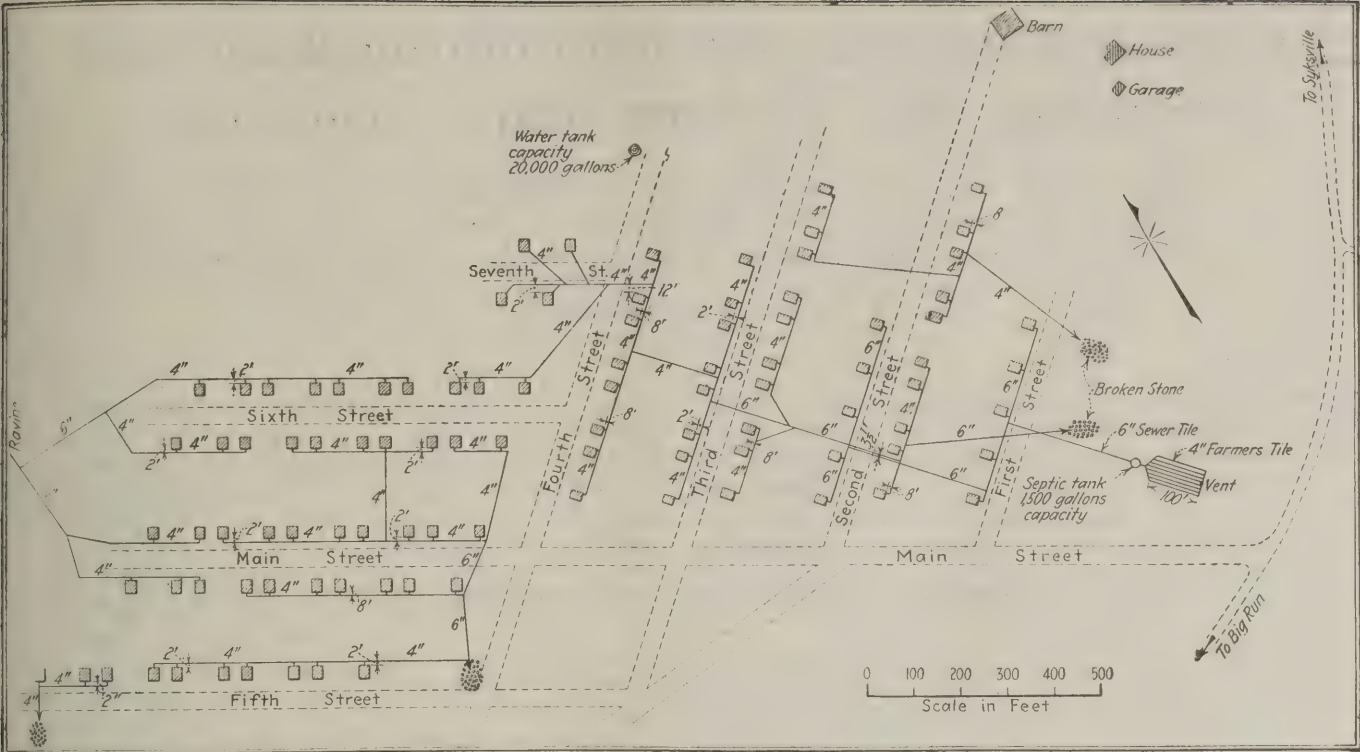

Even a small mining town must have a dependable supply of potable water. Elevating a tank upon a tower as here shown provides not only water storage but also an ample head for fire fighting.

### A Bungalow Front

Round porch columns are more expensive than square ones but add greatly to the appearance of the structure. The weight of the porch is supported by 3-in. pipe columns footed on small concrete piers. This is a detail conducive to low maintenance.

Map of the Town Showing the Two Sewage Systems

Two distinct systems of sewage disposal are here installed. One serves the houses provided with bathrooms and the other those not so provided. One system discharges to a septic tank and the other to surface disposal.

on the main streets with 4-in. terra-cotta pipe and connected to the houses through 3-in. pipe of the same material. These tile are set below the frost line. Waste water, not absorbed by the loose ground in which the open-joint sewers are buried, runs by gravity to the discharge point located in a ravine some distance from the town.

Sewage from the ten seven-room houses on the sanitary system is carried away in 6-in. sealed-joint terra-cotta pipes laid on a 3-per-cent gradient to a central septic tank. The capacity of this tank is 1,500 gal. All joints in this sewer line are sealed with a mixture of one part sand and one part cement.

Outside toilets are provided for the tenants occupy-

ing the houses not equipped with bathrooms. Two toilets and two coal bunkers are built under the roof of one outhouse serving each pair of houses. The two toilets surmount an open concrete vault.

It is now the belief of the company that it would have been to its advantage to install only one sewage system, and that of the sanitary type. Aside from all considerations of sanitation, the closed sewer system which discharges into a septic tank involves a lower maintenance cost.

All streets in the town are lighted with 75-watt lamps. A 2,300-volt circuit is carried from the mine plant to the center of the town, where it is stepped down to 110 volts by being passed through two 15-kva. transformers. This furnishes lighting current to both streets and houses.

Simple System of Sewage Disposal

After passing a septic tank the sewage flows to a system of drain tile, through which it percolates to the soil. The tile in this case acts as a filter for a liquid already purified by the septic tank.

In a recent lecture on the industrial uses of nickel, aluminum bronze and other non-ferrous alloys, delivered before the Institute of Metals in London, says the *Colliery Guardian*, W. M. Corse stated that the production of nickel was largely confined to the British Empire. The bulk of this metal is used in steel manufacture. The outstanding characteristic of aluminum bronze is its resistance to corrosion, although it possesses hardness and strength to a high degree. Curiously enough, it was stated, however, the largest single use for this alloy was for the manufacture of a worm wheel for Ford trucks, for which purpose 11,000,000 lb. had been bought during the past few years. The service records of these gears indicated a low percentage of breakage and a long life. Important work is being done both in Great Britain and the United States on stainless iron and stainless steel alloys, which contain nickel and chromium, and much is expected from experiments now in progress.

# Care in Choosing and Maintaining Fuse and Switches May Prevent Many Accidents\*

Keep Fuses in Fireproof Cabinets—Automatic Circuit Breakers of 2,000-Amp. Capacity or Over Should Be Remotely Controlled—Each Phase in a Three-Phase Circuit Should Be Provided with Separate Fuses

BY J. F. MAC WILLIAMS

Power Engineer, Pennsylvania Coal & Coke Corporation,  
Cresson, Pa.

**F**USES for electrical circuits may be divided into several classes. Link fuses of the open type should be used only when mounted on non-combustible and non-absorptive material. It is always preferable that they be installed in fireproof cabinets. This type of fuse is exposed, and consequently the probability of a short-circuit or injury to anyone working around the fuse or making a renewal is always imminent. The only advantage that this fuse has is that it is relatively cheap.

Inclosed fuses of the plug type are much safer than link fuses of the open type, but even these fuses may be misused and thus prove ineffective. It is a common practice for some men to insert a piece of metal about the size of a penny in the base of the socket and thus make the fuse inoperative. Whenever this type of fuse is used the line wire should be connected to the center contact and the load wire to the threaded part. If this is done the circuit becomes dead the instant the fuse is turned loose from the bottom or line contact. In consequence it is much safer for the workman who has to handle it.

The inclosed type of cartridge fuse also is safer than the open-link type, and when provided with ferrule contacts may be used on circuits carrying currents as high as 60 amp. When equipped with knife-blade contacts the fuses are suitable for use on circuits carrying much larger currents. Some of these fuses which have renewable links may be misused to carry a higher current than that for which they are designed. Even non-renewable cartridge fuses often are tampered with and made inoperative or fused to limits much higher than those for which they were designed by jumper wires being connected between the two terminals.

The inclosed externally operated fuse switch probably is the safest for general work. To renew the fuse the terminals are first of all entirely disconnected from all live parts. The Underwriters' classification of this complete unit is A.A.

Whatever type of fuse be used on a circuit it is always necessary that it be installed and maintained

properly. If this is done few accidents will occur. When renewing fuses in grounded cabinets care should be taken to avoid short-circuits or accidental connection with the ground. All contacts should be kept clean and in proper alignment; otherwise excessive heating may occur and cause serious damage.

Automatic circuit breakers will afford much better protection to apparatus than almost any type of fuse. Usually these breakers are designed so as to trip at any current value between certain limits for which the breaker has been made. Such breakers should be installed high enough from the floor and in such a position that neither the operative nor any inflammable material will be exposed to the arc which rises from the contact tips when the breaker opens.

They should be equipped also with a hand trip properly insulated and in such a position that the breaker may be readily opened manually without injuring the operative's hand or arm or exposing him to the arc. Such a breaker should always be set to trip at a current value much less than that which would cause injury to any connected apparatus or cables. Automatic circuit breakers used for interrupting currents higher than 2,000 amp. should be remotely controlled so as to avoid possibility of danger to the operative if any part should fail when the circuit is being opened.

Automatic reclosing circuit breakers, if installed outside the power plant or substation, should be inclosed in a locked fireproof box to prevent anyone tampering with them. The key should be placed in the hands of a responsible person, familiar with electrical equipment.

This type of breaker is designed so that it will close just as soon as a short-circuit or overload has been taken off the line. Therefore, great care should be taken to avoid shock or burns. To obviate danger when repairing such a switch, or feeder wires connected to it, the control circuit should first of all be opened and the circuit grounded. Unless this be done the workman might begin to work on either the circuit breaker or one of the feeders when the power is off and later the circuit breaker might close, giving him a severe shock or burn.

\*Article entitled, "Electrical Starting Devices," read Oct. 2 before the Mining Section meeting of the National Safety Council, Louisville, Ky.

If circuit breakers are properly installed and maintained the danger of burning out generators, motors or cables and injury to attendants will be reduced greatly. Automatic reclosing circuit breakers may be installed so as to sectionalize feeders and trolley circuits and thus localize any trouble. They also have another advantage in that they may be adjusted so as not to close on any load which would be injurious to the generating or converting equipment.

There are many types of so-called safety switches.

**Busbar Grounding Terminal**  
A clip like this may be easily slipped over a busbar and connected to a good ground.

position when the switch is closed. This handle has a socket at the end which must be entered into a slot in an extension at the lower right-hand corner of the box. The shaft operating the switch is protected by this extension so that it cannot be operated with a wrench or plier. A lineman wishing to work on the circuit controlled by this switch opens the switch and unlocks the handle, which he takes with him. In this way he is assured that no one will close the switch without his knowledge.

Oil switches often are required to open circuits carrying currents much larger than those for which the switch is designed. The oil in these switches is provided in order to prevent arcing when the current is interrupted. These arcs carbonize the oil, thus reducing the insulating characteristics and possibly causing trouble. Dust and dirt also enter the tanks and in many cases form conducting material.

**KEEP OIL USED IN SWITCHES CLEAN**

Whenever an arc is broken under oil the oil dissipates some of this heat and itself becomes heated. This causes an expansion of the oil, expelling a certain quantity of air from the tank. When the oil cools and contracts, new air enters the tank. If this air contains moisture, which it nearly always does, fine particles of water vapor form on the sides of the tank and drop into the oil.

If much moisture and dirt is permitted to collect in the oil and tank, a heavy arc may cause the switch to explode. Switches of this type with vertical contact boards permit dust and dirt to drop into the tank rather easily, whereas horizontal boards prevent a large part of the dust from getting into the oil. Dust and dirt collect on the outside of a switch owing to the presence of oil, which holds any particle of dirt which comes in contact with the switch. Common dust and dirt in this manner form a conductor between the switch terminals and often cause leakage of current to ground or from one line wire to another.

To avoid accidents it is therefore necessary to keep the switch as clean as possible and make periodic

One manufactured by the V. V. Fittings Co. appears to give satisfaction. This switch is enclosed in an iron box and is provided with a curved operating handle locked in

**Pole-Mounted Clip**

Because this grounding terminal is mounted on an insulated pole there is little danger to the workman even should he attempt to place it on a "live" conductor.

inspections of all the current-carrying parts and also of the oil. Sludge in the bottom of an oil tank may become so deep as to cause current to leak from one of the line wires to the ground. If the switch is not grounded the tank and supports will become charged and dangerous.

How often the oil should be changed depends on the service which the oil switch is required to perform. It may be necessary to change it every month or only every few years. In dusty damp places it may need renewal every few months. In dry clean places it may be necessary to renew the oil not oftener than every four years. No general rule can be formulated, as the time will depend on the location and severity of the service. Every oil switch should be inspected at least once a year. If the contacts are damaged they will, of course, increase the probability of accidents.

**FREQUENT INSPECTION SAVES TROUBLE**

At the mines of the Pennsylvania Coal & Coke Corporation, unless a switch has been in abnormal service, it is inspected once a year. If moisture or sludge appears in the tank it is cleaned out, the contacts adjusted and the oil entirely renewed. Any oil which appears to be satisfactory is tested before it is used. Oil that appears to be good often is found, upon further inspection and test, to be unsuitable for use until filtered. For this purpose a pressure filter press is used.

New or filtered oil must not break down at any lower voltage than 35,000 when tested between sphere gaps  $\frac{1}{2}$  in. in diameter and set 0.15 in. apart. The flash point should not be lower than 171 deg. C. and the fire point not less than 178 deg. C.

Graded-resistance types of motor starters are used on both alternating and direct-current circuits. These starters have a number of contact points or small switches which must be periodically inspected. Perfect contact should be made at each point to obtain results.

Most of these starters are provided with a blowout coil for preventing serious arcing. These coils must always be kept in good condition; otherwise they will not function properly, and serious damage may result. When shutting off the current with this type of controller each contact should be broken quickly; unless this is done, the controller cover may be blown out under severe conditions, and the operator injured or a fire result.

A compensator is a combination switch and transformer and is therefore subject to the same dangers as already mentioned and should be protected and cared for in the same manner as other switches.

The wedge-type contacts make a more perfect connection than other types and consequently greatly reduce arcing.

When properly designed and maintained, automatic motor starters are the safest equipment to use for starting motors. They can be located where there is little danger of fire or accident to the operator and can be made to perform their duty accurately each time they are used.

If six motor leads were brought out of delta-connected induction motors each phase could be protected independently by six fuses or relays. With this

**Fuse Socket**

Just as soon as the fuse is partly unscrewed it becomes "dead" if the line and load are connected in this manner.

**This Fuse Is Efficient, Safe and Readily Mounted**

An efficient fuse suitable for outdoor service is important on any outside electrical circuit, but more especially is it important that it should be so constructed that it will not be ruined the first time it is called upon to function. Frequently one disturbance quickly follows another, and if the line is left unprotected after the first accident due to the breakdown of fuse apparatus the result may be disastrous.

arrangement better protection could be afforded the operative and equipment.

Line fuses always have been a great source of trouble and danger to power users and power companies. The Pennsylvania Coal & Coke Corporation has found, after several years' experimenting with many different types, that the Schweitzer & Conrad Type E ejector cutout, though perhaps more expensive than others, gives satisfactory results. This fuse is simple and compact; the fuse element proper consists of a strip of high-resistant high-tensile strength fusible wire which is held in tension by a coil spring. The fuse is provided with slots for quick insertion under terminal screws and enclosed in a cork which protects it from corrosion and also acts as an arc barrier. The cork itself is enclosed in a tube, so there is little possibility of the fuse being affected by external atmospheric conditions. The complete operating mechanism is enclosed in a bakelite tube which is screwed to the operating handle. Current passes from the base of the coil spring to the fuse element through a flexible copper cable. This cable shunts the spring, and therefore the current in the spring is negligible.

#### SPRING BREAKS HEAVY CURRENT ARC

When the fuse link is broken from any cause whatever, the spring contracts and introduces a long gap between the two fuse ends in the tube. This quick and positive rupturing feature is assisted by the barrier effect of the cork. The result is that if the fuse operates on an overload barely sufficient to melt the fuse link, a positive break is obtained. In case of a short-circuit, the cork is ejected by the explosive action of the arc, and besides acting as a barrier it helps to interrupt the arc by sweeping it out of the fuse tube.

The whole fuse outfit is mounted on a crossarm at such an angle that any flame or gases escaping from the open end at the bottom are directed away from the lineman. A new fuse is put into position by a quick motion. This is important if the operator is closing the circuit on an extremely heavy load.

If oil switches were designed so that it would be necessary to open the switch before a short-circuit or

ground could be applied, a great step toward protection of the operative would be accomplished.

In the short-circuiting and grounding-compartment type of switches, the ground connection should be made first. If the doors on the compartment are hinged at the top they should not be removed but swung forward sufficiently that the operative will be able to reach by them and apply the connection to the switch. By this procedure the door will act as a barrier in case the switch is charged.

When men are working on lines the conductors should be grounded and short-circuited. The ground connection should be made first and the short-circuiting devices applied afterward. This should be done whether the work is to be performed inside the plant or outside on the line. The apparatus for this work should consist of flexible cable of a size not less than No. 6 having for station work a clip, which hooks over the ground bus and locks in place.

On the other end of the cable a set of spring clips fitting the contacts of the line terminals and mounted on wood handles should be used. For grounding outside-line wires a piece of  $\frac{3}{4}$ -in. pipe not less than 5 ft. long with a connection head on one end and a point on the other should be used. A clip similar to that mentioned above, made of copper and mounted on wood handles, should be used for attaching to the line wires.

#### DANGERS ARE LESSENERED BY GROUNDS

Ground connections should be made to provide safety to equipment, to discharge abnormal potentials and to afford a path for current leaks from equipment. Such means will reduce the hazards accompanying the operation of electrical apparatus. Sometimes it is not feasible to ground electrical apparatus, and often by doing so the hazards to the operator are increased rather than decreased. In any case, the grounding of equipment, supports, etc., must be understood to be done for the protection of the operative from shock should these parts become charged. Grounded-frame parts actually increase the danger of shock to the operative should he make contact between current-carrying parts and grounded-frame parts. All ground connections should be tested occasionally so as to be sure they are always effective.

A low-voltage release with short-time limit will be found preferable to the no-voltage release when equipment may be subjected to severe shock by a sudden restoration of normal voltage. The short-time limit prevents the complete interruption of service if the drop of voltage and its return is rapid.

Linemen always should use line protectors such as line hose, tie caps, rubber pigs, etc. These men also should use transformer-fuse pullers whenever they are required to remove or install fuse plugs on transformers which may be either heavily loaded or in damaged condition.

#### PROVIDE WORKMAN WITH TESTER

Some simple form of tester for determining whether the line wires are charged often has prevented serious injury to persons required to make repairs. A simple and cheap tester, called the Pocket Electroscope, that can easily be carried, is made by the Minerallac Co. of Chicago. It is the practice of the Pennsylvania Coal & Coke Corporation to furnish its men with this instrument.

Welders should be provided with lenses of suitable quality for protecting the eyes. Such glasses should give maximum protection against ultra-violet and infra-red rays. Combinations of red and blue, or red and green glasses give fair protection, but we are using at present a metallic glass which appears to give our welders less trouble than other glasses. Frames for helmets should be made of a material which will not conduct heat or light. To avoid danger of burns operatives should be required always to use asbestos gloves and aprons.

Rubber gloves should be subjected to a mechanical test. Any 2-in. section of the rubber should stretch to 6 in. without injury. All gloves not used in conjunction with an outer protecting cover should be at every point at least 60 mils thick. Gloves used with outer protecting covers should not be less than 50 mils thick. Variation from these thicknesses should not be more than 15 per cent. An air test for punctures in gloves is easily made by rolling the glove from the cuff toward the finger tips. By moistening the glove, leakage at any point can be easily observed. When immersed in, and filled with water, all gloves when tested with 10,000 volts for 2 minutes should show no leakage in excess of 10 milliamperes.

#### ELIMINATE FALSE IMPRESSIONS OF SAFETY

In laying out a new wiring installation all conductors should be arranged so as to indicate to the workmen the pressures of the different wires. Colored cables and conductors, also insulators and supports, may be used to indicate the pressure of the conductors. Where many different circuits are laid out together it is sometimes possible to arrange those conductors carrying the highest voltages in places where they will be safest. In some installations it may be possible to locate conductors carrying high voltages on the uppermost arm or rack.

When using insulated wires it is well to use only conductors having an insulation which under nearly all conditions could never become dangerous. If this cannot be done, bare wires should be installed, as they can in no way convey to the workmen a false idea of security. Many people have been injured by mistaking weatherproof for insulated wire. These accidents probably would be much less frequent had the wire been bare.

All cable sheaths and conduits carrying conductors should be grounded. Metal tags may be placed on cable sheaths indicating the voltage carried by the conductors, and end bells or potheads should be plainly marked. All cables or wires should receive a test of two and one-half times their working pressure soon after being installed.

#### PUT DANGEROUS APPARATUS OUT OF REACH

It is hardly necessary in these days to install a switchboard having any parts at the front of the board carrying high-voltage circuits. It is wise to use rubber matting if proper care is taken of it—that is, if it is kept clean and dry; otherwise it may become a menace. Wooden platforms, in my opinion, are dangerous. It is easy to stumble over them; they absorb oil, and if not carefully made the nails or screws in them may easily defeat their purpose. Any device installed as a safeguard is more dangerous than nothing at all if it is defective, as the attendant is misled into thinking he is safe when actually he is in great danger.

#### Do We Fuse Three-Phase Circuits to the Best Advantage?

The figure on the left shows the usual method of fusing three-phase systems. Fuses of smaller size which will respond to conditions in each phase may be used if inserted as shown in the figure on the right.

All switches should be opened and closed as quickly as possible, and the blades and contacts should be perfectly aligned so that this may be done. Otherwise there may be serious arcing.

Switch handles should be strong and well insulated. Fiber guards should be provided to prevent switches being closed on circuits which should be left open. Any switch connected to a circuit where there is a possibility of any flashing should be provided with barriers of non-absorptive and non-combustible material. In general, disconnecting switches on 2,200-volt circuits or higher should be provided with such barriers.

Arcing horns for taking up surges, flashovers and overloads should be installed so that neither the operative nor equipment will be in danger when the horns come into action. They should be installed only in places where the arc will not cause damage to overhead equipment. If located in a low position or near other apparatus, side barriers should be installed. The horns themselves should have sufficient spread so that any arc passing along them will be quickly interrupted.

Almost any expense incurred in making electrical equipment safe is a good investment. Where operators feel secure from shock or other accidents, better care usually is given to it, and it is better operated. By eliminating dangers to the equipment and also to the operatives, much expense occasioned by delays and damage is obviated.

#### TAKE PRECAUTIONS BEFORE ACCIDENTS OCCUR

Any reasonable expense incurred when endeavoring to select good electrical equipment for almost any job may easily be justified over a period of years. However, it is also important that the apparatus be installed in the best approved manner. Too often do we see expensive high-grade equipment purchased for a mine and either left unused until it is badly rusted or else it is installed in a careless way. It is not sufficient for the mine officials to merely appropriate large sums of money for the purchase of electrical equipment. The expenditure of such money is justified only when the apparatus has been properly installed and is truly effecting the savings originally claimed for it.

Workmen should be taught the essential details of the equipment they are called upon to operate or maintain. With a perfect knowledge of the function of each coil, relay or contactor the operative will not attempt to use electrical devices which when in disrepair increase the hazards to himself and others. Most accidents are due to ignorance or carelessness, therefore, safety precautions should be started, not when an accident has occurred but before equipment is purchased or installed.

## A Mine That Is One of the Showplaces of Utah

### Black Hawk Mine Portal and Tipple Operated by United States Fuel Co. at Hiawatha, Utah

This mine is generally considered the principal operation of the company. The mine operates in a seam of coal 28-ft. thick and is capable of producing nearly half a million tons annually. More than 300 men are employed when the mine is in full blast. Every safety precaution applicable in Utah is used in this property. Its mine equipment and methods are such that they grip

the attention of any visitor, as might be suggested by the massive concrete portal and three-track main haulage shown in the picture. The mine opening is a drift high in the side of a mountain. Trips are hauled to the portal by motors and let down the hill by tramway to the five-track up-to-date steel tipple illustrated at the top of the page.

# Coal Seams of Alabama—Their Output, Analyses, Ash-Fusing Point and Geologic Structure

Steep Pitches, Thin Seams, Faults and Large Partings  
Frequently Make Operation Difficult but Some Beds Are Clean  
and Flat—Coking Coal Will Suffice to Smelt All Iron in Field

BY MILTON H. FIES

Vice-President, De Bardeleben Coal Corporation,  
Birmingham, Ala.

**P**IG IRON was manufactured in Alabama many years before the mining of coal. Iron ore and red-cedar charcoal were used for that purpose. Tradition says that Alabama iron was used to shoe the horses of Andrew Jackson's soldiers. No coal was produced until 1830. In that year it was mined in Tuscaloosa County, in the vicinity of what is now the University of Alabama, and shipped on flat boats—obviously during the wet season, for there were many shoals—down the Warrior River to Mobile.

About that time the first railroad, the Decatur & Tecumseh, was being constructed in northern Alabama to overcome the obstructions to freight traffic caused by the now well-known Muscle Shoals in the Tennessee River. This railroad was patterned after a railroad at Mauch Chunk, Pa., which was used for hauling anthracite from the Panther Creek Valley. The Alabama railroad, which required about four years to complete, was forty-six miles long and was used solely for the transportation of cotton. Although it was a failure, it demonstrated the practicability of the undertaking, and the succeeding railroads, which were begun in 1834, 1848, 1852 and 1853, added immeasurably to the development of the coal resources of the state.

Between the years 1830 and 1860 practically all the coal mined in the state was dug from the outcrop near the river or from the river beds and shipped by boat to Mobile. The transportation of coal down the Warrior River was a risky proceeding, required much skill and frequently was accompanied by heavy losses. It is recorded that this coal was sold to the gas company in Mobile in 1844; it probably was mined from the Black Creek seam.

In 1914, on the completion of Lock 17, the Warrior River became a navigable stream from nine miles above Cordova, Ala., to Mobile. It offers a great opportunity for the future development of the coal resources of the state.

Coke for foundry use was first made in Alabama in 1855. It was twenty-one years later, however, in 1876, that pig iron was made from Alabama ore with Alabama coal.

Coal and ore mines in Alabama during the "War between the States" aided the South materially and caused great concern to the federal government until federal troops, in 1865, captured the iron works and coal mines. This war awakened the nation, and the South especially, to the possibilities of Alabama's resources. Since that time, notwithstanding difficulties and obstacles, the growth has been most marked.

The perfection of the process of the manufacture of open-hearth steel from Alabama pig iron, on Thanks-

giving Day, Nov. 30, 1899, marked the beginning of substantial development in Alabama. The production of coal for the twenty-four years 1900-1923, inclusive, was 355,583,769 tons; the production for the preceding twenty-four years was 74,329,369 tons. To the perfection of the open-hearth process no small part of this increase is due. After the consummation of this process large producing companies that were making pig iron began comparing the coal and ore resources and, in the main, adopted the policy of withdrawing coal from the commercial markets.

## COAL SEAMS MAINLY OWNED IN FEE

The coal seams in Alabama are owned mainly through fee or mineral rights, although a number of operations pay a royalty on the coal they mine. The royalty paid varies from 5 to 7c. per ton on the low-grade high-ash coals to 15 to 20c. per ton for the best-grade coals. The nature of the ownership of coal lands determines to a large extent the percentage of recovery from a given area. As it has been found costly to mine pillars under land where the surface is owned by individuals, the size of pillars left to protect the surface is of prime consideration. Some coal companies in this state where the ownership is in fee leave such large pillars between rooms that they can be recovered easily by robbing, but when such companies are in possession of the mineral rights only, pillars of sufficient size only to support the surface are left, and consequently they are lost. Longwall or semi-longwall mining is prohibitively expensive where the surface is not owned by the coal company.

In Alabama coal seams, where the coal lies close to the surface, are prospected mainly by sinking test pits on the outcrop, at intervals of about  $\frac{1}{4}$  mile, and then tying up these prospect pits with levels. Where the acreage is large, it is not uncommon to put down diamond-drill holes into the body of the property, even though coal along the outcrop persists in thickness, quality and regularity as to elevation. When the development of a coal property is proposed, with only the coal showing on the outcrop and then pitching into the body of the property, prospecting is done along the outcrop, and where the pitch is not too great or the basin shown by geological study not too deep, drillholes are put into the body of the property. Where the depth of the coal prohibits diamond drilling, geological study of the strata above the coal is made to determine the probable persistency of the seam.

In a region where the coal seam changes, both as to direction and character, without warning and in comparatively short distances, this latter method is not satisfactory, and development following such prospecting involves great risk. In one case where seven

NOTE—First part of article, entitled "Alabama Coal-Mining Practices," to be presented at the Birmingham meeting of the American Institute of Mining and Metallurgical Engineers.

Table I—Coal and Coke Production in Alabama, 1870-1923

Year	Coal	Number of Men Killed	Tons Produced per Life Lost	Number Employees per Life Lost	Coke
1870	13,200				
1871	15,000

1923	20,919,303	89	235,048	133	4,689,641

from the actual mining of coal in these basins has furnished tangible information and the risk has been eliminated.

Table I shows production of coal mined in Alabama from 1870 to 1923, the number of men killed, the number of tons produced per life lost, the number of employees per life lost during the same period, and the tons of coke produced annually from 1880 to 1923, inclusive. Table II shows the tons of coal produced from the various seams, according to counties, for the Warrior, Plateau and Coosa fields for 1923. Table III shows the production from the Cahaba field, according to counties and seams, for 1923. Table IV shows the average number of days coal mines worked in the ten most important coal-producing states, according to compilation of the U. S. Geological Survey, from 1917 through 1921. Table V shows average analyses, as furnished by the U. S. Bureau of Mines, covering all seams mined in Alabama, together with the fusing temperatures of the ash.

Fig. 1 illustrates typical sections of thirty seams mined in the state. The production of the mines is used as follows: Railroads, 30 per cent; other steam users, 13 per cent; furnace companies, 43 per cent; domestic, 10 per cent; bunker, 4 per cent.

The average distribution by states of Alabama's production of coal is as shown in Table V.

About 60 per cent of the coal produced is put through a cleaning process, for which washeries and mechanical cleaners are extensively used. The bulk of the coke output produced is used in the blast furnaces of the state.

Estimates of the ore and coking-coal reserve must of necessity be an approximation. A fair estimate of the red-ore reserve has been placed at 1,500,000,000 tons; the brown-ore at 75,000,000 tons. If the high-silica red and brown ore could be rendered available for smelting through concentration, it is probable that the total reserve would be increased by fully 1,000,000,000 tons. However, a method of concentration has not yet been devised.

The estimated tonnage of coking coals in the Warrior field is given at 4,195,328,000. Though the coking-coal reserve, which does not include coals in the Cahaba field, which probably will be used for coking, is in

drillholes were put into a body of coal consisting of 750 acres, and from twelve to fifteen test pits were opened in the outcrop, two faults were encountered in the mining that the prospecting did not reveal.

In the Cahaba field, where the coal pitches and lies in basins, geological study and test pits on the outcrops have been the only means of prospecting. When this field was first developed many operators came to grief; it is only within recent years that a knowledge gained

Cambrian measures. This field is 68 miles long and from 5 to 8 miles wide; it contains a surface area of 394½ square miles. There are eleven basins, not including the "Overturned Measures."

Coal seams in this field are principally pitching. The roof conditions generally are not so good as in the Warrior field, and more pumping must be done. Considerable methane is encountered, which, together with a variation in the pitch and thickness of the seam, makes mining more difficult than in the Warrior field. Columnar sections of the coal strata in both the Warrior and Cahaba fields are shown in Fig. 3.

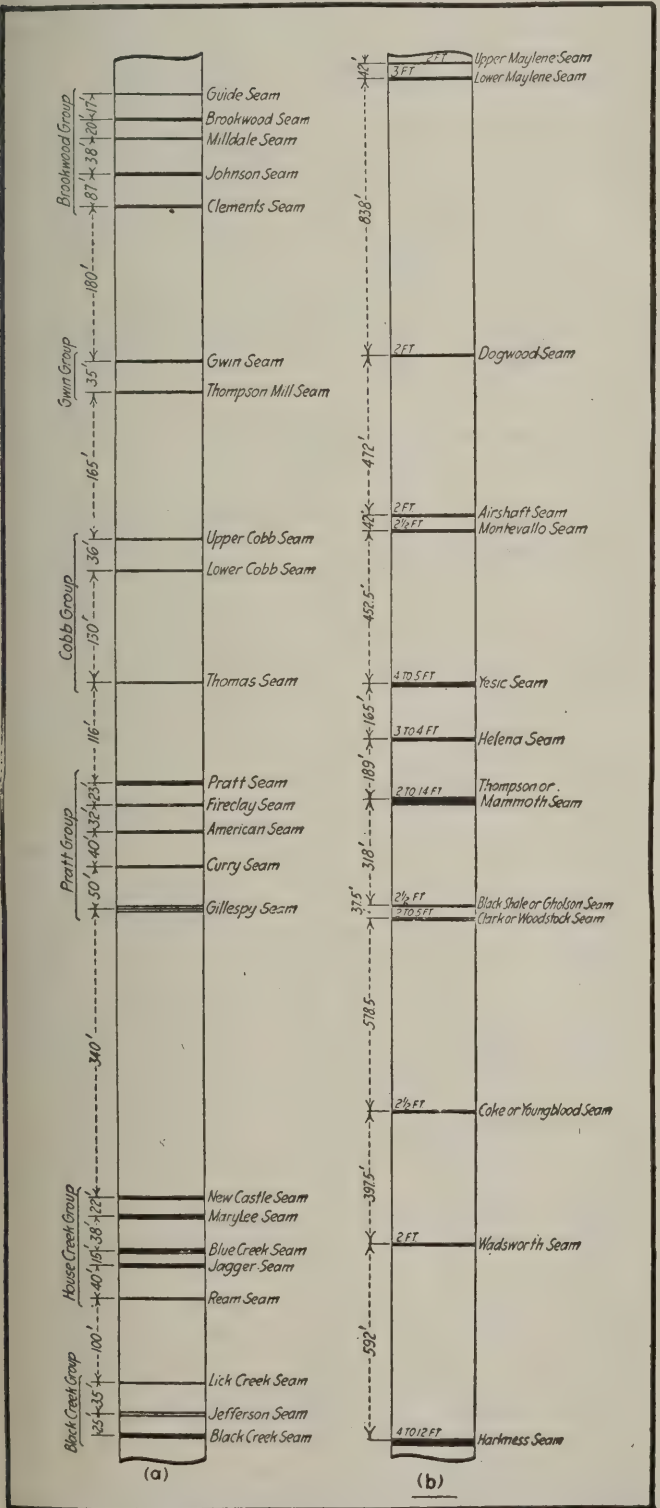

Fig. 3—Sections of Two Important Fields  
Section (a) is in the southeast edge of the Warrior coal basin and (b) is in the Cahaba basin near the town of Montevallo.

Fig. 4—Alabama Mining Is Difficult  
Here is shown in (a) a dislocation fault in the Pratt seam of the Warrior field. A thrust fault (b) is shown along A-A.

The Coosa field lies mainly in Shelby and St. Clair counties and produces little or no coal.

The Plateau region includes those coal measures known geologically as the Plateau field. The Plateau region consists "of the high, wide, flat and plainlike areas of the tops of Cumberland Mountain, Sand Mountain, Racoon Mountain and Lookout Mountain."

Table V—Distribution of Alabama Coal by States			
	Per Cent.		Per Cent.
(1) Alabama.....	67.0	(6) Tennessee.....	1.5
(2) Georgia.....	10.9	(7) Arkansas.....	0.6
(3) Mississippi.....	9.5	(8) Texas.....	0.6
(4) Louisiana.....	8.0	(9) South Carolina.....	0.1
(5) Florida.....	1.8		

The Plateau region, of which the coal measures are a part, comprises about 4,500 square miles. The coal measures in this field never have been mined profitably. Several furnaces north and east of Birmingham were built in this region, with the hope of procuring an adequate and suitable fuel and ore supply; but all of these ventures proved failures as far as procuring raw material in this region is con-

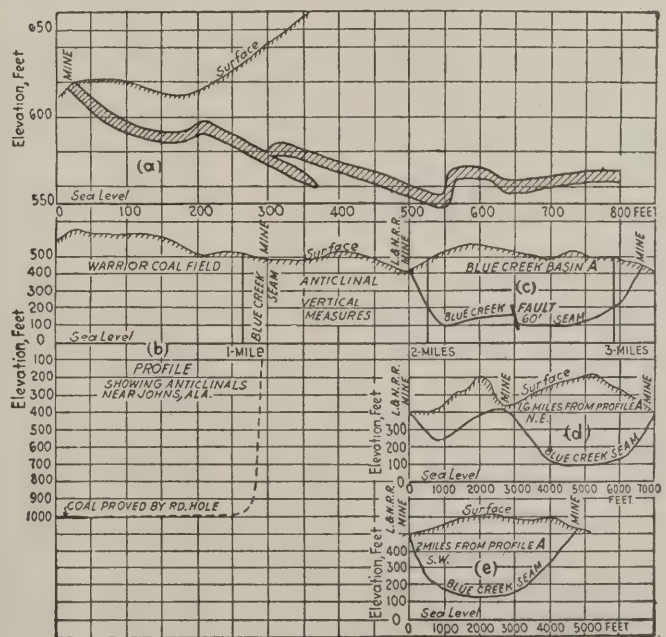

Fig. 5—Blue Creek Basin Conditions  
This region is typical of Warrior field in which there are nineteen faults in nine miles. The sections of this figure are: (a) thrust faults; (b), (c), (d) and (e) regional profiles.

cerned. The coal seams in this field are pockety, irregular and uncertain.

When the term "regular" is applied to coal seams in Alabama it is used only in its geological sense and not with the meaning given by the engineer. In the Warrior and Cahaba fields the chief producers, the pitch, thickness and character of the seams vary greatly in a limited area. Though the examples here cited probably should not be considered typical, they are fairly illustrative of that with which the producers of coal in Alabama must contend.

In the Warrior field adjacent to Ensley the greatest quantity, as compared to all the other seams, of high-grade coking coal has been produced from the Pratt seam. Some idea of the difficulty of coal mining in Alabama may be gleaned from Fig. 4 (a) which shows a profile parallel to and  $\frac{1}{2}$  mile from the outcrop, showing dislocation faults actually proved by mine workings on the Pratt seam in the Warrior field. In nine miles there are nineteen faults, the throw of which varies from 8 to 130 ft., and there is no regularity in the pitch of the coal. In (b) is shown a thrust fault along A-A.

Some of the problems of Alabama coal seams are illustrated in Fig. 5. A profile of the Blue Creek basin of the Warrior field, showing thrust faults, as proved from mine workings, is shown at (a); a profile

Fig. 6—How Coal Lies in Helena Basin

Full lines show proven conditions and dotted lines are a determination of the seams from geological studies.

of the anticlinals near Johns, in the same basin, is shown at (b). At (c) and (d) are profiles through the same basin, (c) being 1.6 miles northeast of (a) and (d) 2 miles southwest. A profile across the Helena basin, in the Cahaba field, is shown in Fig. 6. The full lines represent the seams as proved by mine workings as far as the fault; the broken lines are determinations of the continuation of these seams from geological studies. They give a fair indication of what may be expected beyond the fault.

## Sees Shortsighted Policy in Snatching Britain's European Coal Trade

No Lasting Good in Forcing American Product Into Unnatural Markets  
—Exported Raw Material Can Be Turned to Finished  
Product—British Prosperity Threatened

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

Elation is being manifested in some quarters because the demoralized state of British commerce has given the United States a chance to snatch away some of that country's coal markets in Europe. The American coal trade is not a unit in believing there is any permanent or even temporary good in forcing our coal into unnatural markets. To begin with, our resources of smokeless and gas coals are relatively limited when compared with our deposits of lower-grade coals. It would be in the public interest, it is argued, to have the life of the high-grade fields extended as much as possible, so that that coal could be used to sweeten the output from lower-grade fields. Were well-financed organizations to apply forced draft to the export of this high-grade coal the day would not be distant when it would not be available for mixing with southern Illinois coal, for instance—an eventuality which would spell disaster to the Chicago steel industry.

While there are some in the coal trade, as well as out of it, who think it is bad national policy to export raw materials when we are in a position to turn such raw materials into finished products, the preponderance of opinion is that we should extend our export of coal within reasonable limits. The overwhelming desire is to say nothing that would discourage aggressiveness in foreign trade or the employment of all the keenness we can muster to extend our general commerce. There is present, nevertheless, a decided conviction that we have little to gain and much to lose by attempting to strip the British of markets that naturally are theirs.

Even were it possible for us to take advantage of the present situation, when the British are laboring under great disadvantages, we would contribute dangerously to European instability. More than one-tenth of the people of Great Britain depend directly on the coal industry for their daily bread. England lives by trading, and not by manufacturing. Coal is the keystone in its economic arch. It may be within our power to loosen that

stone a little, but it would bring about unexpected complications.

The United Kingdom and its colonies and dominions are our best customers. Were we to take away any substantial portion of its coal markets, we would decrease in multiplied ratio that country's ability to buy our animal products, our breadstuffs and our machinery. Even were we to sell large amounts of coal in Europe it would be at best an insignificant benefit to one-half of one per cent of our population.

Regardless of what we might be able to do just at this time, it is quite apparent that in the long run we cannot sell any appreciable amount of coal in old-world markets. England is in a similar position with regard to her coal trade as she was with the war. She had to win it and she has to maintain her coal trade. Those who think the British can be permanently dislodged from many of their coal markets are underestimating their tenacity and their skill.

### British Must Use Mechanical Aids

There can be no disputing that the fact that we are in a position at this time to compete with the British in Europe is an indictment of the British industry. It is evident that it must undergo a decided psychological change and must find some way to make extended use of mechanical aids, but it will work out its salvation eventually.

Just at present one of the important things in the interest of the success of the Dawes plan and the rehabilitation of our European customers is to interfere as little as possible with that process. England, with all its financial solvency, is likely to be less prosperous soon even than is Germany. It is equally as important in the stabilization of Europe and more important to the United States, in particular, that Great Britain be restored to prosperity just as Germany is being restored.

Those who contributed the thoughts on which this article is based were careful to point out that their remarks apply only to overseas exports and not to the coal shipments going to Canada. This business must be

### Labor Portfolio for Lewis?

Speculation is going the rounds in official circles at the national capital as to the reward Mr. Lewis is to receive in the event of a Republican victory at the polls. His name is being mentioned in connection with the labor portfolio. If for any reason he is not chosen for that post, it is expected fully that he is to be given some other important place.

The consensus in Washington seems to be that Warren Stone, president of the Brotherhood of Locomotive Engineers, had the better of the argument with John L. Lewis, president of the miners' union, in regard to the operation of the brotherhood's mine in West Virginia. Politically, Mr. Stone suffered severely and his reputation as a trade unionist has been hurt badly.

kept on all fours with our internal commerce, all agree. In building up our coal trade with Canada we have assumed an obligation which we must continue as long as it is in the market for our coal. Every time there is a strike in this country someone shouts for an embargo against shipments to Canada, but even during the most critical shortage of the war period no thought ever was given to any suggestion which would differentiate between the allotments accorded our states and the Canadian provinces.

### Railroads Place More Orders For Equipment

The American Car & Foundry Co. has received an order for 600 mine cars from the Berwind White Coal Mining Co., and the Pennsylvania Coal Co. has placed an order for 100 mine cars with the Pressed Steel Car Co.

The Clark Car Co., of Pittsburgh, has received an order from the Tennessee Coal, Iron & Railway Co. of Birmingham, Ala., for four 30-yard extension side-dump cars. The Lehigh & New England has given a contract for the repair of 300 gondola cars to the American Car & Foundry Co.

Officials of the leading equipment companies expect further large car inquiry in the near future. The Atchison will come into the market for 5,000 additional freight cars and more passenger coaches and the Burlington is likely to inquire for 2,500 additional freight cars soon.

## Britons to Make Study of American Explosives

Washington chemists entertained at dinner Sept. 21 in honor of Prof. E. C. Bailey, of the University of Liverpool; Prof. F. G. Donan of the University of London; Prof. J. F. Thorpe of Imperial College, London; Sir Richard Threlfall and Sir Robert Robertson, explosives chemist for Great Britain.

Prof. Fritz Haber, Director of the Kaiser Wilhelm Institute of Physical Chemistry, of Berlin, was in Washington on the day of the dinner and it was suggested that he be included among the guests. This raised determined protest from certain of the Washington chemists and no invitation was extended to Professor Haber.

Professor Thorpe and Sir Robert Robertson have come to this country to make a study of American explosives.

While British coal mines have made more progress in the application of rock dust to prevent explosions than has been accomplished by American mines, they have not been so uniformly successful in developing safe types of explosives. The U. S. Bureau of Mines is to conduct tests for the English explosives-testing station on British "permitted" explosives, to determine wherein they differ from the "permissible" explosives approved by the Bureau of Mines for use in gaseous and dusty coal mines. This work is being done in pursuance of an arrangement for the exchange of information between the British and American mining bureaus.

C. Lorimer Colburn

Recently resigned from the staff of the U. S. Bureau of Mines to enter private practice as a consulting mining engineer at Denver, Colo. During the last three years Mr. Colburn has become well known as a safety engineer, having been assigned in 1921 to co-operate between the U. S. Bureau of Mines and National Safety Council. He visited the coal-mining membership of the council to assist them in enlarging their safety program. During the past year Mr. Colburn has been serving as director of the Joseph A. Holmes Safety Association, and the number of chapters has been doubled and the influence of the chapters has been increased. Most of the safety chapters have been organized at coal-mining operations. During the World War Mr. Colburn was a captain of engineers.

## Mine-Supply Houses Merge; \$2,500,000 Involved

More than \$2,500,000 is said to be involved in a deal announced Sept. 18 whereby the Banks Supply Co. of Huntington, W. Va., acquired a majority of the stock of the Miller Supply Co., one of the largest mine, mill and railway supply houses in the Huntington district. The capitalization of the Banks Supply Co. will be increased to \$1,400,000.

The Miller company and its branches will be consolidated with the Banks company as soon as possible and the personnel of both organizations will be held intact, it was said. J. C. Miller, W. J. Harvie and T. G. Tinsley, all of the Miller firm, will be added to the directorate of the Banks Supply Co. and another director will be elected by the stockholders.

## Anthracite Circular Prices For October, 1924

(Gross Ton, F.O.B. Mines)

	Broken	Egg	Stove	Nut	Pen.
Lehigh & Wilkes-Barre.....	\$8.00	\$8.75	\$9.00	\$8.75	\$5.75
Pattison & Bowns.....	8.90	8.90	9.15	8.90	5.50
Phila. & Reading.....	9.15	9.15	9.40	9.15	6.00
Lehigh Valley.....	8.50	8.75	9.05	9.05	5.75
Lackawanna.....	8.00	8.75	8.75	8.75	5.75
Lehigh Coal & Nav.....	9.25	9.25	9.50	9.25	6.00
Del. & Hudson.....	9.00	9.00	9.00	9.00	6.00
Thorne, Neale & Co. (Temple Coal Co.).....		9.20	9.55	9.20	5.75
M.A. Hanna & Co.....	8.80	9.15	9.65	9.25	5.75

Prices for steam sizes, as quoted by companies are as follows: Buckwheat No. 1, \$3 @ \$3.15; rice, \$2 @ \$2.25; barley, \$1.50; birdseye, \$1.60.

## Output and Value of Coal from Illinois Mines in 1923

(Compiled by U. S. Geological Survey)

## West Virginia Produces 18.4 per Cent Of Country's Soft Coal

**H. L. Gandy Tells Operators of State's Importance in the Industry—  
Seven Roads Handle One-Third of Total Shipped—  
Industrial Concerns Returning to Coal**

"West Virginia has 18.5 per cent of the present value of the bituminous development and future reserves, according to the Engineers' Valuation Committee of the U. S. Coal Commission," said Harry L. Gandy, executive secretary of the National Coal Association, at a meeting of the West Virginia Coal Association at White Sulphur Springs, W. Va., Sept. 19, 1924. "During the year 1923, according to the production figures of the U. S. Geological Survey, the West Virginia output of bituminous coal was 18.4 per cent of that of the country, being exceeded only by that of Pennsylvania.

"The product of the West Virginia mines and quarries, according to the last census figures, was 9.3 per cent of the total value of the products of mines and quarries in the United States. Great strides have been made in the production of bituminous coal and I feel quite sure that with the excellent railroad facilities here available, the day will come when the percentage of West Virginia manufactured products will be much higher.

Speaking of the relationship of the bituminous-coal industry to the prosperity of the railroads, Mr. Gandy said: "Seven railroads, the Norfolk & Western, the Chesapeake & Ohio, the Virginian, the Louisville & Nashville, the Illinois Central, the Pennsylvania and the Burlington, loaded about 175,000,000 tons of bituminous coal last year. That was nearly one-third of the year's production and considerably more than one-third of the total amount shipped by rail. These roads received \$279,626,648 for handling bituminous coal, which is 32.6 per cent of the total revenue received by all railroads of the country for handling that commodity.

"From the best data available these seven lines used 41,335,760 net tons of bituminous coal in 1923 at a cost of \$117,664,595, or about \$2.85 per ton. The amount spent for bituminous coal was less than half of the amount received as revenue for handling bituminous coal. Thus we have seven of our important coal roads spending for the bituminous coal necessary to move practically all of their traffic, only about 42 per cent of the amount received as revenue from that commodity.

"It is further interesting to note that while these roads received \$279,626,648 for handling bituminous coal, their total gross operating income, after deduction of operating expenses, was \$280,241,861.

"The public knows but little about coal. Most people order coal for their homes or their places of business without any more thought than would be exhibited by a man going into a store and ordering a suit of clothes made out of cloth, without specifying the kind of cloth. There are perhaps as many varieties of coal as there are of cloth. There are varying kinds for all uses and conditions. The right kind of coal

for a particular use will carry its load to the satisfaction of the user. Not only should there be more widespread information regarding this treasure house of heat and of power but there should be a dissemination of information as to the derivatives of coal. We are only a few years along the way in the extraction of byproducts, and I dare say that the coming years have in store great progress in the better utilization of coal.

"No less eminent an authority than the Director of the Geological Survey recently pointed out that a less percentage of the electricity for public utilities was generated by water power in 1923 than in 1919. That can mean nothing else than that the demand for electricity has grown faster than the development of water power. More and more industrial concerns are finding out that with tranquillity in the coal world the question of the use of coal or of oil is an economic one and these two fuels are finding their correct place. A careful perusal of trade papers and other sources of information shows that the order of the day in New England and other parts of the East is that industrial concerns are again returning to coal.

"There is a significance in the establishment of service bureaus by the anthracite industry to increase the satisfactory utilization of their product and in the widespread and persistent effort of manufacturers to sell and place oil-burning devices.

### Form Research Committee

"Recently, however, the National Coal Association has created a Research Committee to the end that there may be gathered and disseminated among the operators and the public fundamental facts which may be helpful in advancing the use of the product of this industry.

"Day after day we read of consolidations that are taking place in the bituminous-coal industry, but even so they are not keeping pace with consolidations in other lines of business and of trade, and are in no sense affecting the competitive situation. I have been impressed for some time that affiliation of purchasing agents and combinations of the users of coal are worthy of the serious consideration of the operators.

"Heretofore we have been inclined to think of a combination as one which gathered together various units of the same kind of production. Now we have great combinations under which there is being gathered all sorts of units of production. For instance, take the circulars which, according to press reports, recently went to Ford agents in the Northwest, advising of the shipment of coal mined at Ford mines, loaded into Ford cars, hauled on a Ford railroad, transported in Ford freighters and unloaded on the Ford docks at the head of the lakes. All of these are in

### Iowa Miners and Operators Join to Advertise

An advertising campaign to be financed jointly by the operators and mine workers will be opened Oct. 7 by coal-mine operators and miners of Appanoose County, Iowa, to continue seven months. Twenty-two mining companies and approximately 3,500 miners in Sub-district 1 of District 13, United Mine Workers are co-operating in the campaign. The operators have agreed to contribute an amount equal to that raised by the union. It is estimated that \$49,000 will be raised.

addition to many other units of different kinds of production owned by that concern. Combinations of that kind are not in violation of the law, but their size and the effect they have on the business and industrial life of the nation will bear following very closely."

### Coal Exports Fall in August; Canadian Shipments Low

Total bituminous coal exports from the United States during August, amounting to 1,392,862 gross tons, showed a decline from shipments during July, when 1,630,849 tons was exported, but have been exceeded during 1924 by only June and July shipments, according to the Coal Division of the Department of Commerce. A large part of the decrease was due to smaller shipments to Canada, 1,049,346 tons being exported in August against 1,202,400 tons in the preceding month.

Overseas exports of bituminous coal during the month in question were 335,671 tons against 418,500 tons in July. A considerable part of this decrease was caused by smaller shipments to Italy, only 89,040 tons going to that country during August against 115,055 in the previous month.

In the South American trade important decreases were witnessed in shipments to Brazil, the August exports amounting to only 80,892 tons against 104,959 tons in July. There were no August shipments to Argentina or Chile, although exports to those two countries during July were 19,104 and 6,905 tons, respectively. The total exports to South American destinations during August were 90,389 tons as compared with 139,098 tons in July.

Exports of anthracite during August amounted to 257,090 tons against 290,097 tons in July, the decline being mainly due to decreased shipments to Canada.

Total shipments of coke amounted to 42,308 tons in August against 48,983 tons in July, the decrease being largely due to smaller shipments to Canada, 34,953 tons in August against 40,438 tons in the preceding month.

Mother Jones, nationally known friend of the coal miner and champion of union labor, called at the White House Sept. 26 and pledged her support to the President. She said no man or set of men control the labor vote.

## Enjoins Tennessee Miners Against Coercion; Right To Strike Is Recognized

Five local unions of the United Mine Workers, their officers and several hundred individual members, all of whom were named, in Grundy and Marion counties, Tennessee, were enjoined Sept. 20 by Judge Xen Hicks, of the U. S. Court for the Eastern District of Tennessee, in a sweeping order against interfering with the operations of any of the mines operated in these counties by the Tennessee Consolidated Coal Co.

In addition by means of a restraining order members of the union were forbidden to enter the houses of the company which they have been occupying since a strike by the miners began on April 1.

In the opinion Judge Hicks said, in part:

"In these labor disputes, labor—the miners in this case—has the right to strike, the right to refuse to work, the right to use all peaceable means to persuade others not to work, the right to use all peaceable persuasion, the right to assemble for that purpose and to congregate in halls for that purpose, but it has no right to go to the extent of violence, threats, coercion and intimidation."

In discussing this particular case the opinion goes on to say: "It must be admitted that the situation in Grundy and Marion counties is estranged and the feeling intense. All the coal mines have been shut down since April 1. The coal drum of the New Whitehall Coal Co. was blown up with dynamite at a loss of between \$8,000 and \$10,000 when an attempt was made to operate."

Judge Hicks also cites in the opinion the action of a county sheriff who appointed union men as deputy sheriffs to maintain order. The sheriff was scathingly criticized in the opinion, which stated that some of the very defendants had been named as deputy sheriffs for the purpose of arresting themselves.

On the other hand contentions of plaintiff's counsel to term action of the miners in seeking to maintain the wage scale of 1920 throughout the country by the national and district unions as "a conspiracy" was not upheld in the opinion, which stated that though such action might be a conspiracy, it was not an unlawful conspiracy and the miners were within their rights as long as unlawful threats and intimidations were not used.

The unions enjoined were Local 2763, at Tracy City, Grundy County; Local 3509, at Palmer, Grundy County; Local 2572, at Coalmont, Grundy County; Freemont local, Grundy County; Local 4185, at Morganville, Marion County, and Local 1778, at Cartwright, Marion County.

The international organization of the United Mine Workers of America, its officers and Provisional District 19 and its president, William Turnblazer, against whom injunctions were sought, were not enjoined, the opinion stating that insufficient evidence was submitted against these defendants.

## D. H. Pape Joins N. C. A. Staff

Delbert H. Pape, of Ogden, Utah, has joined the staff of the National Coal Association as assistant to Harry L. Gandy, executive secretary. Mr. Pape will devote his attention largely to field and membership activities.

Mr. Pape is 40 years of age and has had a broad experience in coal production. After receiving a high school and

Delbert H. Pape

business college education, he went directly into the mines, working under every classification of labor up to and including the position of foreman.

From 1914 to 1922 he was general manager of the Lion Coal Co., at Ogden, Utah, embracing the Wyoming Coal Co. and the Union Fuel Co. in Wyoming and the Wattis Coal Co. in Utah. In co-operation with P. J. Quealy, of the Gunn-Quealy and the Kemmerer coal companies, he helped organize the Southern Wyoming Coal Operators' Association, and during the war was appointed by United States Fuel Administrator Dr. H. A. Garfield as distributor of coal mined in southern Wyoming, which appointment was made upon the recommendation of all other Wyoming operators and the Union Pacific R.R. officials.

## 'Patronize Home Industry' Move in Indiana

Miners and operators in the Hoosier coal fields are considering starting a campaign in the state to induce coal consumers to buy coal produced in Indiana, instead of buying non-union coal from other states, according to officers of the United Mine Workers. Similar campaigns have been started in other states and have proved successful, it was said. Indiana, according to officers of the mine workers' organization, consumes a large amount of coal that comes from Kentucky and West Virginia. There is no good reason, they say, why consumers should send out of the state for coal when they can obtain just as good coal at home.

## Safety Congress Session Opens in Louisville

Contending that the trade and other associations should co-operate in promoting safety, Richard F. Grant, president of the Chamber of Commerce of the United States and president of the Susquehanna Collieries Co., made the opening address at the Monday morning, Sept. 29, session of the thirteenth annual congress of the National Safety Council at Louisville, Ky., at which a large number of executives and safety men were present. Mr. Grant was the spokesman for an association which itself represents a larger number of representative bodies than perhaps any other in the United States. Other speakers were Norvin E. Green, president of the Louisville Safety Council, and Huston Quin, Mayor of Louisville.

The treasurer's balance showed for Aug. 31 \$4,589 on hand and \$47,290 invested. The total assets less depreciation were \$84,438, with accounts payable of \$3,047.

In the afternoon the Secretary of Labor, James J. Davis, discussed the fundamentals of our industrial safety problem, and Dr. Arnold L. Jacoby, director psychopathic clinic, Detroit, Mich., showed how mental factors entered into the accident problem, making some men more prone to casualties than others.

C. F. Kettering, of the General Motors Research Corporation, discussed the public-safety problem, declaring that 99 per cent of our actions are dominated by instinct rather than by intelligence and that instructions to workers must be repeated with painstaking care. If this is not done the instructions progressively deteriorate. "Jamie" Heron, of Chicago, spoke on ways of building men for safety, and A. W. Whitney, chairman of the American Standards Committee, reported on the standardization of safety codes. The new National Safety Council film, "A Word to the Wise," was shown.

## Big Panhandle Mines Merged In \$2,500,000 Deal

In one of the largest coal deals consummated in West Virginia in some time John C. McKinley, president of the Richland Coal Co., of Wheeling, acquired the Otto Marmet Coal & Mining Co., with which are associated the Black Betsy and Marmet Halm Coal Co. The deal is said to involve approximately \$2,500,000.

The properties transferred are located in Putnam, Kanawha and Mason counties and include about 11,000 acres of coal in addition to two railroads leading from the mines to terminals and river piers, as well as three boats and a large number of barges. Storage facilities and elevators at Cincinnati also are included.

The purchaser will make improvements to increase the output from 200,000 to 500,000 tons a year.

The new owner operates the Richland-Marshall and Mound Shaft mines, at Moundsville; the McKinleyville mines, in Brooke County; the Richland mine, north of Wheeling, and various other properties in the northern Panhandle.

# Dawes Plan Seen as Stimulus to Widen Markets for American Products

Characterizing the Dawes plan as a boon to the world, "without a liability in it," an authority in an unexcelled position to judge believes the industrial activities it will promote will result in greatly increasing markets for our products, while the greater volume of German goods in the channels of world trade is not likely to affect us seriously.

As things are shaping, keenest competition will arise in iron and steel. Plants in the Ruhr have been re-equipped and brought up to the most modern form because the situation has been such that profits could be invested best in equipment. Some working agreement is certain to be made between the producers of the raw material in Lorraine and the steel makers in the Rhur. In addition to being one of the world's most favored centers for steel manufacture, the Ruhr will have an additional advantage, for a time, in that the standard of living has been reduced greatly and low rates of wage will be acceptable. The living standard will rise gradually, but the steel makers will continue to enjoy an advantage until this differential in their favor is overcome.

Our industry is preparing to meet this situation by installing more labor-saving machinery. An indication that our manufacturers have on their fighting clothing is seen in their recent success in obtaining an order for 35,000 tons of corrugated iron in Argentina, an order for which the Continental industry was striving.

On the other hand, the British steel makers are in a bad way. Few of their plants are modern. Instead of striving to reduce their costs effort appears to be concentrated on yelling at the government. Both labor and capital in Great Britain seem to have fallen into a psychological rut which is hampering them in meeting the increasing difficulties which they are facing. Such a large proportion of the British trade is with other countries that it is certain to be hard hit by the rehabilitation of Germany. A much smaller proportion of our trade

is export. In addition, we are in a frame of mind which will do much toward enabling us to hold our own in the export market.

An indication of the commercial demoralization which has overtaken the British is had in the fact that an American coal company apparently is in a position to compete successfully with Great Britain for a large block of Italy's requirements.

Our technical industries are entrencing themselves at home by a great expansion in the practice of mass production of standardized goods, which because of their low price are finding increasing markets abroad—a stronger position than that occupied by the German industry, which in catering principally to the foreign trade cannot take advantage of the economies of quantity production, but must meet the diverse requirements of many lands. There is every reason, however, for our manufacturers to start at once to increase their selling efforts abroad.

Russia at this time is making substantial purchases here of cotton, machine tools and certain other commodities. No confidence can be placed in the future of Russian trade. The establishment of buying commissions in foreign countries, including the United States, tends to bear out every pessimism which has been expressed in connection with the commercial policies of the Soviet authorities. Absolute control of purchasing centers in Moscow. Purchases are shifted quickly for political reasons. The German police, for instance, raided one of the Russian offices and in retaliation all the buying being done in that country was discontinued and transferred to other countries. Similar action was taken when the Russian authorities were displeased by developments in Italy and Switzerland.

This is a new phenomenon. No permanent commerce could be built up under such conditions. An official in Washington might make a nasty remark about the conduct of affairs in Moscow and our manufacturers would

## Mines Bureau Engineer Reaches Mine Disaster Via Air Mail Service

Dr. Hubert Work, Secretary of the Interior, on Sept. 24 addressed this letter of thanks to Postmaster General New for the speedy transportation of a U. S. Bureau of Mines engineer by the Air Mail Service to the scene of the mine explosion at Sublet, Wyo., Sept. 16:

"Permit me to thank you for the recent co-operation extended by the Air Mail Service of your department to the Bureau of Mines of this department, in responding to the call for aid at the recent mine explosion near Sublet, Wyo. The Bureau of Mines engineer of that district, on reaching Cheyenne, found that he was unable to get a train to Rock Springs for many hours. He accordingly requested the Air Mail Service to transport him from Cheyenne to Rock Springs, and, on official confirmation of the request, this was done. As this was a situation in which the lives of miners were imperiled, the action of your department in co-operating to provide speedy transportation to the scene of the disaster was especially appreciated."

find the business they had built up transferred over night to some other country. Russia is buying in this country at this time partly to cater to us and partly because prices are lower. Once that recognition has been obtained much of this business is likely to be placed elsewhere to aid in gaining some further objective. The Russian agents, however, are preaching as they buy. They say much larger orders would be placed were Russia recognized. This argument is being pressed in connection with their purchases of cotton, and our cotton trade is taking the bait. Sight is lost of the fact that with any return approximating normal, Russia again will become an exporter of cotton.

## Practical Pointers For Electrical And Mechanical Men

### Bad Mechanical Features Spoil Good Locomotive Performance

Because a Mine Locomotive Is Considered To Be an Electrical Machine,  
Mechanical Details Should Not Be Neglected, They  
Influence Its Operation

Aside from the many electrical details of a mine locomotive which must always be kept in proper operating condition there are equally important mechanical features to be considered. From the mechanical engineer's point of view derailments of mine locomotives may be caused by the following: Insufficient elevation of the outer rail on curves; too great a difference in size of wheels on one axle; the changing of one pair of wheels on a locomotive without changing the other pair; improper location of wheels with respect to the end-thrust point, usually located at the end of the axle; incorrect shape of wheel tread; wheel not bored true; curves too sharp for the wheelbase of the locomotive; locomotive not properly balanced; hitchings to cars made too high, thus unbalancing the locomotive, especially on grades; broken springs on one or more journals.

#### BAD TRACK, BAD RESULTS

The results from insufficient elevation of the outer rail are well known. Too great a difference in the size of wheels on the same axle forces one wheel to slip continually because one side of the locomotive cannot travel faster than the other; this also causes the wheels to climb the rails at curves.

If one pair of wheels is changed and not the other, in many cases the locomotive will travel at an angle to the track instead of parallel to it. Curves in tracks cause the operating part of the tread on one wheel of a pair to move in toward the center of the locomotive and outward on the other. The same is true if the thrust blocks or plates are not properly set. A correctly shaped pair of wheels will move over on a curve so that the inside wheel is turning on a smaller diameter than the outside wheel; therefore, when repairing and machining wheel treads, the exact shape of a new wheel and tread should be maintained.

If the radius of a curve is too small the locomotive will climb the outside rail. If wheels are not bored at right angles to the tread as they run over the tracks the wheel gage may become too narrow on one-half a revolution and too wide on the other half or, worse yet, cause the locomotive to wobble along the track. This produces a changing wheel gage from too wide to too narrow and increases the liability

of the wheels to drop through or climb the rails.

If the locomotive is not properly balanced the high end tends to climb the rail at curves. This same result will be produced if the car hitchings are too high and the trip heavy. Broken journal springs tend to unbalance the weight on the wheels.

If a deep groove is allowed to wear in the wheel treads the slipping-over effect on curves to compensate for the difference in rail length is prevented. The false flange thus formed pounds the frogs and damages the locomotives and track. Locomotive frames must be kept tight and square; otherwise all parts are under a strain and the axles do not stand at right angles to the track and the wheels cannot run parallel.

J. F. MACWILLIAMS,  
Power Engineer.

### Oxy-Welding Made It Better Than New

Every shop in the country working with metals may not have among its equipment a punch press of such dimensions as the one illustrated here. Still there are few shop owners that are not faced at one time or another with the specter of a shutdown because of damaged machinery. Thus the main point in the following incident should be interesting as typical of the wide variety of repair and reclamation work done by welding.

We may start with the statement that when broken equipment is carefully repaired with a reinforced oxyacetylene weld it is stronger at the repaired section than it was originally. Some skeptics might say, "Yes, probably," or "Undoubtedly, in laboratory tests, but does the same hold good in practice?"

It does! But to answer the question most satisfactorily is to prove it.

Fig. 1 shows a punch-press frame, a gray-iron casting weighing approximately two tons. A piece of metal too thick or tough broke the casting squarely off at the level of the table. The frame was cracked through a hollow rectangular section 19 in. wide, 20 in. deep, 6 in. thick at the front, 1½ in. at the back and 2 in. at the sides.

After the edges were carefully cut in a V shape and the frame accurately aligned it was preheated by gas burners and a good welding job done by competent oxyacetylene operators. The casting was carefully covered to protect it from any drafts while being welded, and this covering was left in place until after the casting had cooled.

After proper annealing the punch-press frame was put back in service and stood under the work for a year. Then someone again fed it too big a bite and it broke. Of course the frame was sent to the same shop which has welded it after the first accident. It

Fig. 1—Where First Fracture Occurred

Before this break was welded the joint was carefully cut in a V shape and preheated. A covering used to protect the metal from drafts was left around the frame until the metal had cooled after the weld was completed.

was again repaired and is shown in the second illustration ready for another term of service.

The point in the story is not that one good job deserves another nor that the competent welder is an ever-ready help in time of trouble but that the second break did not run through the old weld. This was left unharmed. Nor was the new break in the region preheated for the old weld. It was in

Fig. 2—Second Break in New Position

The repaired frame broke in a new place when loaded above capacity. The old weld remained intact. The second repair was made in the same manner as the first and the machine was again placed in service.

the crank bearing 4 ft. away. This, then, demonstrates the original proposition, that a second break in a properly made weld need never be feared.

J. F. IRBY.

## Sled for the Mine Yard

A wagon is not always the easiest means of transporting materials about a mine yard. Whenever something is to be moved in a wagon it must be

## Steel Sled, Strong and Sturdy

Materials may be easily rolled or shifted onto this sled. No need to strain workmen's backs or break machine parts due to falls.

lifted into the wagon box and again lowered at a delivering point. Aside from the extra labor required for this work, the damage to equipment due to falls or the injury of workmen often is expensive.

A sled or skid always is handy around a mine yard because of the uneven terrain and the ease with which materials may be loaded upon it. Fig. 1 shows the type sled used at No. 9 Mine of Old Ben Coal Co., West Frankfort, Ill. Fig. 2 shows how the inside of the channel frame has been filled to

make it stronger and easier for the driver to stand upon it.

This sled is drawn by mules and easily slides over the ground because of the smooth steel runners. The upper

## Bottom Channel of Frame

The wooden plank in the center of this channel adds strength to the sled and provides a firm footing for the mule driver.

channels are not filled like the lower ones and therefore provide strong edges to hold materials from sliding off. The ease with which heavy barrels are moved about the property is remarkable.

## Make Forge Coke on the Job

Illinois coal is hard to coke, especially after it has been exposed to the air as has the shallow coal in a strip pit. This small but effective outdoor coke

## Coking Strip-Pit Coal

An inexpensive way to get blacksmithing fuel is this of the Black Servant Coal Co. Instead of using smithing coal it makes its own coke which usually can be done. It will work well if the coal is not too sulphury. The coal in a strip pit often has a low sulphur content, owing to its long exposure.

plant, consisting of a fireclay bowl within a housing of light steel, however, cokes it, supplying fuel for the

forges at the strip pit of the Black Servant Coal Co., Elkhart, Ill., the new "Hartshorn" operation. The pipe seen in the illustration is an air line which drives a blast of air up through the coal.

## Locomotive Batteries Save Money and Get Exercise

Often, when a mine is shut down, electric lights, nevertheless, are needed during the day and night. At such times it is often a problem to decide how the overhead charges can be kept as low as possible. If the boiler plant must be kept in operation and a generator must be in service continually men must be employed to operate them, and that is a heavy charge on an idle mine.

The main office of the Madison Coal Corp., at Glen Carbon, Ill., receives its lighting service from one of the mines nearby. During the summer the mine has been idle and in order to avoid keeping the boiler plant and generator in continual operation storage batteries supply the service.

Occasionally, about once every two or three weeks, the boilers and generator are operated for the purpose of recharging the batteries, but as soon as the batteries are again charged to capacity the power plant is shut down.

## LIGHT SUPPLIED FROM BATTERY

The batteries used for the lights also supply power to the electric repair shop which has been in operation quite frequently during the summer. Here electric repairs are made for all the mines of the company.

In the illustration a locomotive battery is shown in the repair shop. Aside from driving the shop equipment the battery supplies current for lights around the mine and in the main office.

There are many advantages to this scheme aside altogether from the cost of operating the boiler plant and generating unit. Idle batteries deteriorate more rapidly than those in service, and this arrangement furnishes plenty of exercise for the cells and keeps them in good condition.

## Battery Furnishes Electric Energy for Lights and Repair Work

All the electrical energy required during the idle period of the mine is received from this battery set up in the electric repair shop. To recharge the cells the boiler and power plant need be operated for only a day every two or three weeks.

# Production And the Market

## Bituminous-Coal Market Gains in Firmness; Demand, Output and Prices Stronger

Further improvement marked the bituminous-coal market during the last week. In keeping with general business conditions, much of the increase is seasonal, and extreme caution is in evidence throughout the trade. Such barometers of trade as freight-car loadings, however, are indicative of healthy conditions. Advancing prices are due largely to domestic demand, offset somewhat by a tendency toward softness in slack.

Much attention is centered on the developments in western Kentucky, where the non-union drive is making headway. If this movement is entirely successful, it is expected to bring the producers of steam coal in Illinois into the same desperate straits in which are the union fields that compete with eastern Kentucky and southern West Virginia.

### Conditions in Kanawha Field Unsettled

In the Kanawha field, where the operators on the Chesapeake & Ohio are making a determined drive to eliminate the union, two large operators, Mike Gallagher, of the Paint Creek Collieries, and Jim Paisley, of the Kelly Creek Collieries, continue idle. Each of these operators agreed with John L. Lewis to sign the Jacksonville scale, which precludes them from joining the drive to open on a non-union basis. They are remaining neutral by not reopening their mines as union operations, which incidentally they could not afford to do. It is understood that this is a bitter disappointment to Mr. Lewis.

Coal Age Index of spot prices continues to advance, registering its fourth successive weekly gain, the figure as of Sept. 29 being 170, the corresponding price for which is \$2.06. This compares with 169 and \$2.04 respectively on Sept. 22.

Activity at Hampton Roads showed a sharp reaction last week, dumpings of coal for all accounts during the seven-day period ended Sept. 25 totaling 356,557 net

tons, compared with 383,710 tons in the previous week.

Movement up the lakes seems to be definitely on the wane. Dumpings at Lake Erie ports during the week ended Sept. 28, according to the Ore & Coal Exchange, were as follows: For cargo, 734,246 net tons; for fuel, 39,686 tons, compared with 770,331 and 45,957 tons respectively during the previous week.

Output of bituminous coal continues to show marked improvement, the total for the week ended Sept. 20, according to the Geological Survey, being estimated at 9,902,000 net tons, an increase of 373,000 tons over the week ended Sept. 13, when 9,529,000 tons was produced, according to revised figures. Production is now at the

highest level reached since the first week of March. Anthracite output also gained during the week ended Sept. 20, totaling 1,851,000 net tons, compared with 1,820,000 tons during the previous week.

The anthracite market is notably active, the demand for independent coals being good and line companies moving their product without difficulty. There is a heavy call for stove and chestnut has perked up markedly. Egg is moving fairly well also, and though peas is in more limited demand, it is moving without much trouble. Steam sizes are moving more readily, buckwheat showing considerable strength.

### Estimates of Production

	(Net Tons)	
<b>BITUMINOUS</b>		
	1923	1924

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.		

## Midwest Still Active

Although warm weather prevailed for some time prices have not been reduced on domestic sizes of southern Illinois coal. Operators have enough orders to keep every open mine running to full capacity. It is true they are troubled somewhat in moving screenings, but the better grades from this field have not been materially reduced in price. Central Illinois has increased lump price 25c. per ton. Egg and mine-run prices are stationary, but screenings in a few cases have brought only a modest price.

Eastern Kentucky coal is difficult to obtain in gondola equipment, and prices are firm, but shipments are fairly prompt. Pocahontas prices have not been established for October but no material increase is expected. Anthracite prices are expected to remain the same during October as they are at present. All in all the market, as viewed from Chicago, is healthy and nobody is complaining.

In southern Illinois fields there seems to be an epidemic in the demand for lump coal, especially from the Williamson and Franklin County fields. In the last week egg has begun to move, but the mines are oversold on lump for a month or longer. Egg is now oversold for a week ahead. Nut is slow and screenings are not moving. Railroad tonnage and train movement are good. Mines are getting from three to five days a week. All mines have "no-bill" screenings and nut on track. The Mt. Olive field has picked

up with a snap. Domestic coal is moving and the railroads seem to be taking the egg and nut sizes. Screenings are going on contract. In the Standard field the operators are always getting selfish. They are giving their screenings away at 75c. and expect to get \$2.50 or \$2.75 for 2-in. lump when Mt. Olive 6-in. can be bought for the same price.

St. Louis domestic business continues good. This is principally on Carterville grades, although Mt. Olive is coming in strong. Standard is not in demand yet. Anthracite is moving fairly well. Smokeless is showing up better and coke is active. Wagonload steam business is beginning to appear while carload steam is still slow. Country domestic is good but country steam demand is negligible.

## Kentucky Is Busy Too

Movement of coal from the western Kentucky fields continues heavy and at firm prices, with a slight increase in the minimum price on egg and lump from \$2.50 to around \$2.60. The top on these sizes is \$2.75. Block is \$2.75@ \$3. The market is quoted at 85c. to a dollar on screenings. Demand for prepared sizes is so heavy that operating mines are having no trouble in disposing of production. One of the difficulties is in getting proper equipment, flat bottoms being scarce.

All Kentucky demand is strong on prepared sizes, especially the larger ones; though screenings are weaker in

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	Sept. 29	Sept. 22	Sept. 15	Oct. 1
Index .....	170	169	167	196
Weighted average price .....	\$2.06	\$2.04	\$2.02	\$2.37

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

price, demand is good considering present production, as a lot of large steam buyers are now stocking up fall supplies. The general belief is that the market is fairly close to the top for the time being. Eastern Kentucky hasn't any cause for complaint with a good car supply, low production cost and good prices. Non-union mines in western Kentucky are making some money, and union mines paying the full wage scale can make a little money at the present market.

Retailers in Louisville have advanced prices 50c. a ton on prepared sizes, due to the steady advance in mine prices, and report that business is good.

### Northwest Is Not Rushed

Coal business throughout the Northwest eased along during the week without any striking high lights, but domestic movement continued strong. At the Head-of-the-Lakes prices were unchanged throughout the list but a drop is imminent partly because of the steam situation. Heavy recent rains have amassed water power that is expected to replace some steam coal. Big surpluses of screenings, especially of Pocahontas coal, have piled up as a result of extensive business in the domestic sizes.

Thirty-one cargoes, five of them hard coal, arrived at Duluth last week. Sixteen are reported on the way, and of these four are hard. There seems to be no possibility of a shortage there this year, and in fact shipments may be materially reduced as a result of the torrential rains. There is a big demand for anthracite, and Duluth is shipping to the Dakotas and to Winnipeg. It seems certain that Winnipeg will be fed from Duluth all winter.

Twin Cities steam buyers are holding hard to their policy

of refusing to buy beyond immediate needs. The new situation with a 28c. increase on rates from southern Illinois to the Twin Cities places quite a handicap on coal from that region. But the suspension of rates for central and northern Illinois and from Indiana, until Jan. 8, gives those districts a chance to go after business formerly going to southern Illinois, and they are doing it. So the dock trade is not getting the Twin City and surrounding territory for its own as a result of the recent advance in rates.

Twin Cities quotations remain about as they have been. Southern Illinois lump is \$3.25 with screenings \$1.50@1.75. Western Kentucky lump is \$2.50@2.75, and screenings 90c. @ \$1. Indiana lump is \$2.75, and screenings \$1.50. Dock prices are on the same basis as before. Anthracite egg is \$13.20; nut, \$13.45 and stove, \$13.60. Lignite is coming to the district in a much reduced quantity.

The Milwaukee coal trade is experiencing a weather market. The spurt of last week has been followed by a slackening demand. However, a fair movement from the docks is reported. There is a demand for Pocahontas which is hard to meet because the mines are sold up for September and October and Pocahontas has advanced 50c. West Virginia splint also is wanted, and hard to get. Receipts of coal by lake at Milwaukee up to Sept. 24 aggregate 566,454 tons of anthracite and 1,586,210 tons of bituminous coal, a total of 2,152,664 tons. This record for both grades is 514,519 tons below 1923 for the same period.

### West Is Stimulated

Southwestern domestic grades took a pronounced jump during the week, while steam slumped. Operators say the domestic demand would justify opening more mines, if the industrial market were stronger. As a result only a few mines are being reopened. No price changes have been made though some operators are quoting Arkansas screenings as low as \$1 a ton while the current quotation is \$2.

In Colorado the market is much better, thanks to cooler weather. The average working time of the mines in that district last week advanced to twenty-eight hours with only 30 per cent of the working time lost due to "no market." Prices have not changed.

In Utah a cold snap has stimulated demand. Retailers have been working overtime for several days. Salt Lake City's coal yards now have about 50,000 tons on hand. Retail prices are still unsettled. The next increase will doubtless be 50c. a ton on large sizes and 25c. on intermediate sizes. Operators say the consumer business is improving in Idaho and Nevada.

### Ohio Markets Developing Strength

Domestic inquiry and purchases continue strong at Cincinnati. Some October prices have appeared that are much above spot figures. Some Hazard output is quoted at \$3 for block, \$2.50 for egg, \$2.25 for 2-in. and \$1.75 for run of mine. West Virginia offerings also have been advanced. Steam coals, generally speaking, are hanging back and slack has shown signs of softening. Much strength pervades the low-volatile division, though screenings are rather soft. Lake buyers are still in evidence, but no longer are in command. River business still lags because of conditions in the Kanawha fields, the low stage of the water and labor trouble among towboat men. Retail prices are unchanged, most of the dealers waiting to see what happens to the prices after Oct. 1.

Domestic trade at Columbus continues to improve steadily. Demurrage domestic coal is being reduced as the trade improves. Steam buying is haphazard, the larger users buying on the open market. Utilities are good consumers and a good tonnage also is going to public institutions and schools. Railroad consumption is only fair, but some lines of general manufacturing are showing a better buying spirit. Quite a few of the larger mines are being put into commission after lengthy idleness. The lake trade is steady with a fair tonnage moving.

Demand in eastern Ohio was strong enough last week to result in the largest week's output since March, but steam buyers are not in the market to the extent they should be at this time. The domestic market has been so active that spot quotations at Cleveland on Pocahontas and other smokeless fuels have risen 75c. to \$1 per ton. Practically no change is noted in spot prices on steam coals, f.o.b. Ohio mines. Ohio mines are having much difficulty in competing with non-union fields. Increased demand has not

thus far had any appreciable effect on prices. General railroad traffic is steadily increasing. Lake shipping is nearly a finished job, so far as this season is concerned.

Pittsburgh Still Below Normal

Shipments of domestic coal are increasing at Pittsburgh, but the movement is hardly up to normal. Slack is much weaker and quotations are off fully 10c. a ton, following a 10c. decline a week ago. Other prices are unchanged. Reports of the steel trade are of lighter buying of steel and a tendency among mills to reduce operations.

Production in the central Pennsylvania field is increasing, 13,910 cars having been loaded during the week ending Sept. 20, as compared with 13,303 the week previous. "No-bill" cars amount to 1,500. Prices at the mines are as follows: Pool 18, \$1.60@\$1.65; Pool 11, \$1.65@\$1.70; Pool 10, \$1.80@\$2; Pool 9, \$2.10@\$2.20; Pool 71, \$2.25@\$2.35; Pool 1, \$2.40@\$2.55.

The situation at Buffalo grows more quiet from nearly all sides. The demand for slack, which was producing a slightly better price, has fallen off. The attempt to change from anthracite to smokeless coal is not likely to amount to more than a wedge this year. Quotations are about as usual.

Spectacular Recovery in New England

The tidewater bituminous market at Boston has undergone a spectacular recovery, quotations for pool 1 New River and Pocahontas moving from the lowest figure since pre-war days to the highest that has obtained for several months, all within the week. This advance is directly due to a firming in spot prices at the southern loading piers. Demand for coal at Boston also has expanded considerably. At Mystic Wharf discharging ran up to 7,000 tons per day and about an equal tonnage has been discharged at the privately owned wharves. All of the dischargings at Mystic Wharf have gone out to consumers.

Prices have not undergone much improvement at Providence as yet, some tonnage still being available at \$5.30 on cars but that market has been on a higher level than Boston all along.

There also has been a little more action in Pennsylvania steam coal. Some fair business is reported, at good prices, up to \$2.50 net ton mine being obtained for medium volatile coal. Indications are not very promising for any marked expansion in rail coal, for tide coal still has the edge on price.

uying Heavier in Atlantic Markets

Increased buying at New York is indicated by a heavier movement of coal and an increase in inquiries. Incidentally two cargoes of Southern coal arrived here recently consigned to utilities. Reserve stocks are dwindling rapidly toward the danger point should there be any transportation trouble or a shortage of cars. Contract coals are moving better and contract holders are taking larger shipments. Tidewater movement is fair but prices remain about stationary. There is little free Pool 1 coal to be had.

Tonnage is moving better at Philadelphia. Stocks at manufacturing plants, except the utilities, are exceedingly low, but these concerns are buying more than current requirements. Industrial conditions are improving at an increasing pace. More contract coal is moving. On the B. & O. R.R. there is a shortage of cars. There has been more inquiry for contract prices lately and some additional tonnage has been closed for delivery between now and

April 1. Users of gas slack, principally cement manufacturers, have been taking some tonnages of late.

Inquiry at Baltimore continues to grow. Not only is the home market encouraging, but export movement has increased. Buying of industrial coals for storage is coming from the smaller industries. A demand is developing for some of the pools which have been practically stagnant for a number of weeks past.

Gradual expansion continues at Birmingham with small concerns starting up or making better time, which is tending to increase fuel requirements. The cotton-ginning season and activity at oil mills is consuming additional tonnage, and there is a good scattering of spot business. The railroads are increasing the tonnage taken on contracts as transportation conditions improve. Bunker and export trade is still slow.

Anthracite Gaining Headway

Demand is active at New York for anthracite, consumers endeavoring to fill their bins while movement is good. Independent coals are in good demand and the old-line companies are not having any trouble in moving their output. The call for stove is heavy, although chestnut has picked up considerably and is now in remarkably good shape for the New York market. Some of the smaller producers are well sold up on all of the larger sizes and are reluctant to book orders for straight stove coal. Egg also is in fair shape. The call for pea coal is slow but there is no difficulty experienced to move it. Buckwheat No. 1 shows more strength, with rice and barley moving readily.

The slow, steady accretion of business by Philadelphia retailers goes on, helped by cool weather. Stove is in increased demand. Company producers are close to sold up on the larger sizes, with pea the only slow moving size, and this showing more strength. Egg is going a trifle better with all shippers. Retail prices are moving upward. Steam sizes show considerable improvement.

Baltimore dealers report a fair amount of orders, but the volume is not at all commensurate with conditions created by the failure to store over the summer months in the usual amount. Coal men are hoping for an early cold snap to stimulate orders and allow them to get in a fair proportion of this coal before steady cold weather sets in.

Trade at Buffalo shows no tendency to recover as sunny days continue. The independent anthracite trade is quiet. Shippers are holding prices firm at about \$1 above the line prices. Chestnut and stove are most active. Furnace and the small sizes are very slow.

Demand in the Connellsville coke market is very light. Prices, however, show much stiffness, and this is clearly traceable to fear on the part of independent operators that their wage scales, in most cases about one-third below the Frick scale, may be difficult to hold if the Frick company should increase its operations much. Spot furnace coke remains quotable at \$3@\$3.10. Foundry coke continues in poor demand, but prices hold without any difficulty, production being very limited and operators quite indisposed to try to increase operations by cutting prices. Spot foundry remains at \$4@\$4.50, according to brand.

## Foreign Market And Export News

### British Market Dull with Inland and Export Demand Far Below Normal

Shipments of Welsh coal of late have been slightly heavier than during July and August though the prospects on the whole are anything but bright. The inland trade has not expanded and export demands remain considerably short of normal proportions. On an output of slightly over a million tons per week, 10 per cent short of the total of some months ago, there are enormous stocks of coal, consisting chiefly of large coal of secondary and lower grades, and of vast quantities of small coal.

The superior Admiralty classes of coal remain scarce because of the closing of the Cambrian collieries several weeks ago. The result is that qualities are able to maintain prices fairly well. Further shutdowns are feared because of the unremunerative working conditions, the small Continental demand and the fact that Germany is successfully competing for the markets.

The Newcastle market is still in a deplorable condition and export business is very difficult to obtain. German competition in Europe is severely felt. Several Continental gas works are taking quantities up to 20,000 tons at prices averaging 26s. 6d., per ton, and Riga merchants are inviting offers of 25,000 tons of steam coals for shipment this year.

Coal output by British collieries during the week ended Sept. 13, a cable to *Coal Age* states, was 4,907,000 tons, according to the official reports. This compares with a production of 5,180,000 tons during the week ended Sept. 6.

#### Hampton Roads Market Active; Prices Stronger

Hampton Roads reports the best business of the last six months, with the market stiffening and with demand becoming more insistent day by day. Coastwise movement is consuming the bulk of the thought of the trade, together with Western demand and bunkers.

Shippers who were unable to dispose of mine-run coal two or three weeks ago at \$1.60 net ton mines, were unable last week to fill orders for the same at less than \$1.75. Some New England buyers were in the market offering \$4.25 net ton piers for pool 1. High-volatile coal generally was quoted \$4.10 @ \$4.15 at the pier for October delivery.

#### French House Coals More Active; British Imports Slump

The French industrial coal market continues dull but stocks are not of large volume. Business in house coals, however, is increasingly active.

Due to the high level of prices in South Wales, there has been a progressive falling off in imports of British coals. For the same reason smokeless patent fuel is being extensively made and tested in the Paris plants.

The prices of French sized coals for October are unchanged from those of September, ovoids alone being reduced to 117.20f. per ton.

Offers of German coal continue numerous in the open market, but deliveries are slow.

The supply of rolling stock both at the mines and at Rouen has left much to be desired and arrivals have been delayed. In Belgium the crisis is already very acute and threatens to be critical when the transport of the beet crop is in full swing.

Deliveries of indemnity fuels thus far in September have been at a daily average rate of 31,600 tons, as against 28,600 tons per day in August.

Coke deliveries to the O.R.C.A. during the first eleven days of September totaled 145,797 tons, or at the rate of 9,100 tons a day. The price of reparation coke probably will remain unaltered this month at 145.25f. delivered frontier station Sierck, O.R.C.A.'s charges excluded. Although no official statement has been made, it is re-

ported from an authoritative source that the Belgian price of reparation coke is reduced from 146 to 135f. (135 Belgian francs being equal to 126 French francs).

The situation in the Belgian coal market is unfavorable owing to acute foreign competition. The falling off in sales of industrial coals has led to larger price concessions. There has been a fair demand for half-bituminous sized coals, both in the Center and Charleroi coal fields. In dry duffs trading is satisfactory.

## News Items From Field and Trade

### ALABAMA

Chas. F. DeBardeleben, Jr., who has been superintendent of the Overton Mines of the Alabama Fuel & Iron Co., has been appointed general manager in charge of physical properties and operations.

The Southern Ry. will soon begin the construction of a new coal chute at Selma, to cost in the neighborhood of \$50,000, replacing one burned some time ago, according to announcement made by H. A. Debutte, superintendent of the Mobile division of the Southern Ry.

E. F. Powelson and a staff of engineers have arrived in Birmingham preparatory to beginning construction on the large plant of the Hercules Powder Co. to be built on a large tract of land at McAdory, near Bessemer. It is stated that the plant will have a capacity of 1,250,000 lb. of dynamite monthly and will be the most modern of its kind in the country.

In line with the rehabilitation of service on the Warrior River and the provision of additional equipment for the movement of coal and other freight to and from Mobile and other gulf ports, officials of the Inland Waterways plan to buy from the Tennessee Coal, Iron & R.R., 28 barges owned by the latter for a consideration of about \$600,000.

J. M. Cobb, for the past several years foreman in charge of the Birmingham station of the U. S. Bureau of Mines, has accepted a position with the DeBardeleben Coal Corporation as safety inspector at all works of the company.

The Red Star mine, on the properties of the Nelson Coal Corporation, recently acquired by the Pratt Fuel Corporation, which had been idle for some time, has resumed operations on a limited schedule.

Tentative arrangements have been made whereby the Ensley Southern Ry., formerly operated by the Southern Ry. system but recently thrown into the hands of a receiver, will be taken over and operated in connection with the Birmingham Southern R.R., a subsidiary of the Tennessee Coal, Iron & R.R. Co. The Ensley Southern affords Birmingham's only rail connection with Birminghamport, on the Warrior River large line, and its acquisition by the Birmingham Southern will be immensely important to the interests of the Tennessee company and other shippers of the district.

Reports from Jasper are to the effect that L. B. Baird, former Alabama board member of the United Mine Workers,

is sponsoring a movement to organize locals in the Walker County field to be affiliated with District No. 20, which lost its autonomy about a year ago when its ranks became so depleted that the district organization was not self-supporting and had practically ceased to function since the 1920 strike. Better working schedules and more satisfactory conditions have been maintained in Alabama working on an open-shop basis, and indications are that little sympathy will be accorded the movement for reorganization.

### ARKANSAS

The stripping plant of the C. C. & E. Coal Co. west of Clarksville has been bought by Winston Bros. Coal Co., of Minneapolis, Minn. W. O. Winston, Jr., is superintendent of the mine. It now employs 75 men and has a 1,000-ton capacity tippie. The new company has installed a Marion 350-ton electric shovel and it is announced locally that the plant is to be further expanded.

### COLORADO

An offering of \$50,000 joint closed first mortgage 7 per cent serial gold bonds of the Bell Coal Co. and the Bell Mining Co. was recently made at par and accrued interest. The bonds are dated Aug. 1, 1924, and are due \$5,000 annually, 1926-35. The bonds are secured by the total assets of the companies and guaranteed as to principal and interest by the personal indorsement of R. M. Head and J. H. Head. The issue will finance expansion and improvement of the properties and business. The Bell Mining Co. owns and operates the Eureka mine, in Boulder County.

James McKeown is now superintendent of the Bear Canon Coal Co. at Valloroso.

On Sept. 9 a fall of rock in the Turner No. 2 mine of the Calumet Fuel Co., of which he is superintendent, so badly injured James R. Cameron's left arm that it was necessary to amputate it immediately. His foot was broken also. The accident occurred when Mr. Cameron was directing a crew of men in timbering the rock. He saw it moving and shouted to the men in time for them to jump to safety, but was caught himself. Mr. Cameron is well known in Gallup, N. M., where he was employed as engineer and as superintendent by the Gallup-American Coal Co., and in Eckels, W. Va., where he was resident engineer for the Guggenheim interests.

### ILLINOIS

Austin N. Harloy has joined the Columbus Mining Co., of Chicago, to be in charge of the jobbing department and to handle the output of the company's two Indiana mines—the Bright Gem, at Jessup, and the Shamrock, at Riley.

Edward Leming has succeeded John Hayes as mine manager at the Kathleen mine of the Union Colliery Co., at Dowell, south of Duquoin. Hayes has accepted a similar position with a coal company at West Frankfort.

After working for 72 years in coal mines, John Egloff, of Murphysboro, has decided to "lay off" for his first rest. He is now 81 years of age and worked the greater part of his life in the old and now abandoned No. 9 Mine of the Consolidated Coal Co., at Murphysboro.

The Peabody Coal Co. will open its Mine No. 9, at Taylorville, this week. A new tippie has been constructed and other repairs made. About 500 men are employed.

A vein of coal 6½ ft. thick has been struck in the Coonsburg vicinity, near Lincoln, at a depth of 295 ft. This is approximately the same depth as the coal strata under Lincoln. The boring has been financed by farmers, but plans are being made to establish a wagon mine.

C. O. Wager, of the North Coal Co., states that his company is now operating its new mine on the North Main Street road, Kewanee. Coal is being mined from a 4-ft. vein which analyzes very well.

The Valley view coal mine, Coal Valley, has been reopened by its owners, Sackville and Wynn. The mine is now employing thirty-five men. It had been closed since last February.

Coal from the Rutland mine will be upon the market within the next two weeks. It has been over four years since this mine was operated. The Rutland mine was first worked more than thirty years ago and for many years was a prosperous operation.

A small mine is to be sunk on the Ferry farm south of Moline at once by the newly incorporated Highland Coal Co., of Rock Island, whose capital stock is \$25,000. Subscribers to \$11,000 of the stock are Henry Rohwedner, William Ferry; Louis Rohwedner, of Moline; Thomas Thompson, A. S. Thompson and Leroy Dehler, of Rock Island, and J. Hasper, of Cuba.

## INDIANA

New shaker screens, picking tables and loading booms have been installed in the old tippie at the Shamrock mine of the Columbus Mining Co. at Riley.

To satisfy a judgment for \$100,916.66 obtained by the National Bank of Kentucky, of Louisville, against the Big Four Coal Co., arrangements are being made to sell the Liberty mine of the company, near Francisco, with the coal rights, property and buildings. The sale is being arranged for Oct. 10.

Indiana's largest coal mine, American mine No. 1, near Bicknell, started hoisting coal again Monday, Sept. 22, after having been closed for about six months. Because of its size, this mine does not hoist unless conditions are such as to warrant a fair weekly average of working days.

The Standard mine, near Wheatland, is to reopen soon, after having been stopped all summer. The stoppage for lack of market was aggravated by labor trouble. The mine installed coal-loading machines and the men picked to run the machines were called out by the union local. It is said that an agreement has been reached whereby the mine can reopen. This mine's entire output goes to the B. & O. R.R. While it has been shut down the railroad has been using West Virginia coal.

A strike of fire and gas inspectors employed in the mines of the Knox Consolidated Coal Co. in the Bicknell field called for Sept. 22 failed to develop, and the two large mines owned by the company operated. The mines threatened with a tie-up were the Indian Creek, which has been operating with 400 men for about three months, and the American mine No. 1, which has been closed for several months, but had been scheduled to resume operations. The American mine is the largest in the state and it was announced it would employ about 900 men. The threatened strike followed a controversy which began about three months ago, when the company reduced the wages of firebosses 20 per cent. It is reported that the controversy has been settled. Had the inspectors carried out their intention to go on strike, 1,300 miners would have been held out of the mines. There is no rule in the wage agreement providing for a definite wage for these inspectors, the matter being left to agreement between the company and the firebosses.

Increased activity in the Terre Haute and Clinton coal fields in the last few days gives promise that a revival of

the Indiana bituminous industry is at hand. More mines are working now than at any time since last February and optimism for better times is reflected in both miner and operator circles. A controversy between the miners and officials of the Chicago, Milwaukee & St. Paul R.R. over work trains to carry miners from Terre Haute to the mines in the Clinton field has been adjusted after tying up work at several of the mines for a few days.

## KANSAS

W. Capen Shank, Pittsburg, president of the Carbon Coal Co. and identified with other coal interests, may again be a brother-in-law to a Missouri Governor. He held that relationship to Lon V. Stephens, who was Governor of Missouri a number of years ago. Another brother-in-law, Dr. Arthur W. Nelson, is the Democratic gubernatorial candidate in Missouri this fall.

John O'Leary and W. D. Van Horn, international board members of the United Mine Workers, sent into District 14 by President John L. Lewis to make a survey of conditions recommended that a corps of at least two organizers be sent into the field.

## KENTUCKY

The recently organized R. L. Brown Coal Co., Evarts, is planning the installation of electric equipment and mining machinery for the development of a portion of the 500-acre tract of land acquired from the Standard Harlan Coal Co.

W. D. Coil, of Madisonville, has acquired about 3,000 acres of coal land in Pond River County.

It is reported that the fire in the Himyar Coal Co. mines at Domino has finally been extinguished, after a long effort, and through assistance of the U. S. Bureau of Mines. In the original explosion and fire a foreman and two men were killed. When an effort was made later to start the mines the fire broke out afresh. The plant will open in a few days. It employs about 300 men and has a capacity of about 25 cars a day.

The Sandy Valley & Elkhorn Railway Co., belonging to the Consolidation Coal Co., and purchased from the Baltimore & Ohio R.R., in 1922, embracing 31 miles of road, from Shelby Junction, in Pike County, to Dunham, in Letcher County, is fighting an effort of the State Tax Commission to increase its tax assessment \$3,396,579 to \$9,395,113.

The Cumberland Straight Creek Coal Co., at Logan Switch, near Pineville,

lost a \$10,000 tippie by fire on the night of Sept. 11, just after announcement had been made of plans for resuming operations on Monday, Sept. 15, at a reduced scale of wages, the mines having been down since April, because the workers refused to accept the reduction. It is believed that the fire was a plain case of arson, and a reward has been offered by company officials for arrest and conviction of those responsible. The plant is not far from the mines of the Liberty Coal & Coke Co., where several miners were shot last spring, and which resulted in the camp being under military guard for some weeks.

The Hawley McIsaacs Coal Co., at St. Charles, has installed a second stripping shovel in its operation, and expects to produce about 500 cars of coal in September, it having produced close to 250 cars last month. In August the Morrison Coal Co., at Centertown, Ky., produced 549 cars by the strip process, and the Kershaw Coal Co., at the same place, stripped 480 cars.

## MARYLAND

Dr. J. J. Rutledge, chief mine engineer of the Maryland Bureau of Mines, and L. C. Hutson, director of vocational education of the Maryland Bureau of Mines, have established mining classes at Frostburg, Lonaconing, Westernport, Kitzmiller and Mount Savage. Plans also are being considered for classes in other mining sections of the state. The course consists of 33 lessons dealing with all the fundamental subjects relative to the mining of coal.

## MINNESOTA

According to the manager of the Ford coal dock in Duluth, about thirty Ford agents in the Northwest have ordered coal in carloads from the company. As there were notices sent out to 478 dealers, the response does not seem to be sufficiently large to represent any serious tonnage.

Just before the increased rate on coal from southern Illinois became effective, Walter H. Newton, of Minneapolis, representative from the Fifth Minnesota district, wired a protest to the Interstate Commerce Commission against the increased rates becoming effective, and asking their suspension and a reopening of the case. The rates took effect, however.

## MISSOURI

The Reed Coal Co., of Fulton, will start stripping coal on the Gohring farm, three miles west of Fulton, at once. The company's steam shovel will be used in the operations. About 26 acres of coal are to be taken out, J. F. Reed, head of the company said.

## NEW YORK

O. W. Seaberg has been elected a vice-president of the Steamship Fuel Corporation of New York City and will also continue his former duties as sales manager. Mr. Seaberg has been connected with this company for some time

**Hospital and Doctor's Office at Hanna, Wyo.**

This is one of the towns of the Union Pacific Coal Co. in a small coal field many miles east of Rock Springs.

and is well known to the coal trade. Other officers of the company are Sanders A. Wertheim, president, and J. J. Ferranto, vice-president. The Wyoming Valley Coal Co., of which Mr. Wertheim is the president, now has fourteen retail yards located in various cities. Of these three are in Brooklyn, two in far Rockaway, two in Newark, two in Cedarhurst, L. I.; and one each in Jamaica, Springfield, Mass.; Bradley Beach, N. J.; Long Branch, N. J., and Red Bank, N. J.

J. F. Birmingham, president of the Delaware, Lackawanna & Western Coal Co., has resigned as a director of the Delaware, Lackawanna & Western R.R. The vacancy was filled by the election of Charles C. Smith, of New York.

## OHIO

Owing to lack of demand the Elk Coal Co. mine at Roseville has been closed down indefinitely, throwing about 150 men out of employment.

Joe Darlington, general manager of the Cowan's Creek Coal Co. at Ice, Ky., with Alex Vowles, also of the operating end, were in Cincinnati recently conferring with the owners of these mines concerning further improvements to the mechanical equipment.

Fire of unknown origin recently totally destroyed the power house and boiler room of the Mid-Hocking Coal Co., at Corning, causing a loss of \$11,000. Steps will be taken to rebuild the power plant.

The Essex Coal Co., has put into operation the Lost Run and Jacksonville mines, which had been idle for some time.

The Northern Fuel Co., which has headquarters in Toledo and of which H. H. Heiner, Jr., is the head, has opened a Columbus office with W. S. Courtright, formerly with the New Pittsburgh Coal Co., in charge.

Mines of the North Hocking Co., near Murray City, employing about 125 men, are about to reopen. The mines have been shut down since last February.

## PENNSYLVANIA

The Logan Coal Co., Philadelphia, has removed to Rooms 1018-1022 Packard Building, 15th and Chestnut Streets.

Shamokin Coal Co., of New York, under Delaware laws increased its capital from \$1,500,000 to \$1,625,000.

Cornelius Brislin, treasurer of the Warrior Run local union of the United Mine Workers, is being held in the Luzerne County jail on a charge of embezzling the entire funds of the local, amounting to \$2,700.

Officials of the A. S. Van Wickles estate have announced that there has been no agreement reached in the proposal of the Lehigh Valley Coal Co. to buy the boundary pillars between the Beaver Meadow colliery of the Lehigh Valley and the Coleraine mines of the estate. Coleraine, which was started 83

years ago and which after being abandoned twice has made fortunes for three sets of operators, is about worked out. Robbing pillars was the chief method of gaining coal for years.

On the afternoon of Sept. 20 eighteen teams representing seventeen mines gave an exhibition near West Newton, of their excellent training at the first annual first-aid contest of the Pittsburgh Coal Co. First place was given to the team from Montour No. 9 mine, which nosed out the Champion mine team by a small margin, the scores being 98.39 and 98.28 per cent. The teams that participated were chosen from a field of 1,000 men who were trained last winter by instructors from the U. S. Bureau of Mines and local physicians. Final selections were made during three months of intensive training prior to the contest.

Resumption of operations at the Weston colliery of the Dodson operating interests after a strike that started July 21 has already boosted coal tonnage carried over the Hazleton and Mahanoy Division of the Lehigh Valley R.R.

The Lehigh Valley Coal Co., Lytle Coal Co., Lehigh Coal & Navigation Co. and Philadelphia & Reading Coal & Iron companies are named defendants in a suit instituted by J. Stanton Christ, of Berks county for alleged damages for coal dirt washed down the Schuylkill River upon his land.

Ten miners were injured, one perhaps fatally, at the Lance colliery of the Lehigh & Wilkes-Barre Coal Co. near Plymouth when a cage lowering them to work dropped 40 ft. to the bottom of the shaft. The accident occurred when the steam reverse refused to work.

A new washhouse and carpenter shop for the Glen Alden Coal Co. are under construction on the property adjacent to the Baker colliery, in the Bellevue section of Scranton. The washhouse will be a one-story structure of brick, steel and concrete 48 x 78 ft. in size. The carpenter shop will have concrete footings and floor, steel frame and corrugated-iron sidings and roof. It will be 40 x 60 ft. in size and one story high.

The Buckeye Coal Co., subsidiary of the Youngstown Sheet & Tube Co., at Nemacolin mine, is installing a skip hoist in the main slope and a turn-over cage at the material shaft for hoisting rock in solid end cars, which is all that will be used at that mine. An endless-rope car haul to feed the railroad cars past the tipples as they are loaded also is being installed. This is one of the most modern mines in western Pennsylvania, and since being sunk three or four years ago, has been operating with temporary hoisting equipment. This mine is at Nemacolin, Washington County, on the Monongahela River, about twenty miles above Brownsville, on the Pennsylvania R.R. The mine continues to operate while this work is being done.

Business is improving so much in the Connellsville coke region that the H. C.

Frick Coke Co., subsidiary of the United States Steel Corporation, has started up the Continental No. 1 plant, near Uniontown, firing 200 ovens, one-half of the ovens at the plant, which had been idle for several months. The Oliver & Snyder Steel Co. also has fired 100 ovens at each of its three plants near Uniontown, and the Lincoln Coal & Coke Co. has reopened its mine and blown in some of its ovens at Keister, between Brownsville and Uniontown. All of these plants had been idle for several months. The Vesta Coal Co., subsidiary of the Jones & Laughlin Steel Corporation, has resumed operations at its No. 6 mine, a union mine on the edge of the coke region, in Washington County, on the Monongahela River, after being idle for eight weeks.

Surveys are being made of the coal banks of the old Harleigh Brookwood Coal company's colliery at Harleigh now part of the Markle holdings, by James W. Boyle, of Freeland. His coal company, the Harleigh Coal company, has leased these and will run them through a washery for preparation for market of the small sizes contained in the banks. It is planned to erect frames, screens and buildings in the next month and to have things moving by the time the demand for small sized coal develops.

The Tri-District Board of the United Mine Workers, in session at Wilkes-Barre, recently decided to notify diamond drill operators and crews engaged that they must become members of the miners' union. It was declared that these men come under existing agreements and that they should be subject to union jurisdiction. About 80 of these men are employed in the three districts. The board also concurred in the recommendation of the American Federation of Labor indorsing La Follette and Wheeler and Congressional candidates approved by the independent party. Circular letters were ordered sent to all local unions in the anthracite districts urging the support of the La Follette-Wheeler ticket.

## TENNESSEE

The Liberty Coal Mining Co., 421 Decatur Street, Memphis, has increased its capital from \$75,000 to \$100,000.

The Richland Coal Co., Inc., of Dayton, of which E. M. Williamson is president, has mines under development at Soddy, near Montlake. Daily output is to be about 200 tons.

## TEXAS

L. W. Stephenson, of the U. S. Geological Survey, is in Texas for several months to be engaged in field studies of the upper Cretaceous and in work on the new state map.

## UTAH

William Littlejohn, general superintendent at Castle Gate for the Utah Fuel Co., suffered a broken leg in an automobile accident Sept. 10 while driving on the Park road near the head of Horse Creek canyon.

L. F. Rains, president of the Carbon Fuel Co., Salt Lake City, acted as grand marshal in the twilight parade in Salt Lake City on Defense Day.

Preparations are in progress for a resumption of operations by the King Coal Co., originally known as the Star mine, at Musselshell, within a short time. The property has not been worked for several months owing to the depressed condition of the coal market. A rearrangement of the surface plant is planned and it is reported that the management will place a considerable number of men on the payroll.

## VIRGINIA

The Norfolk office of the Logan County Coal Corporation, in charge of H. M. Fadley, will be moved to Richmond, Oct. 1.

## WASHINGTON

In the process of reorganizing the Corbin coal interests, the Corbin Coal & Coke Co., capital \$10,000,000, was permitted by the Superior Court at Spokane to dissolve on Sept. 9. The interests of the company have been taken over by Corbin Coals, Ltd., a British Columbia corporation with a capital of \$5,000,000, according to the concern's lawyers. Only part of the stock of the Corbin Coal & Coke Co. had been issued. The British Columbia corporation controls several coal mines in that province.

## WEST VIRGINIA

The principal office of the Oriole Coal Co. has been moved from Huntington, W. Va., to Pittsburgh, Pa. The New Howard Coal Co. has changed its principal office from Sprigg to Huntington.

Among West Virginia Coal companies that have surrendered their charters are the Candace Coal & Coke Co., the Colgate Coal Co. and the Virana Coal Co. The Penn-Mary Coal Co. has withdrawn from the state, mines formerly operated by it now being operated by the Bethlehem Mines Corporation.

The Buchanan Coal Co., at Buchanan, in the Fairmont region, with a normal output of about 2,000 tons per day, which has been idle for several months, started a small operation last week, at a reduced wage scale of about \$3.50 per eight-hour day for inside drivers, tracklayers, etc., and \$3 per day for outside labor.

Henry A. Phillips, of Pittsburgh, has increased his coal holdings in Clay district of Monongalia County through the acquisition of four tracts aggregating 285 acres of Pittsburgh coal. The undivided half interest in one tract of 160 acres, purchased from D. Richard White and wife, brought \$24,000 or about \$300 an acre; 30 acres on Jakes Run, \$6,048.75; 10 acres brought \$2,020, and 84 acres on Thomas Run brought \$16,885.80.

The Pond Creek Pocahontas Coal Co., subsidiary of the Island Creek Coal Co., of Holden, is putting in a new mine to tap 3,000 acres of Pocahontas

No. 4 coal which lies at a depth of 600 ft. on Dry Fork, McDowell County. A man shaft and a main shaft to be equipped with skips have already been sunk and a new tippie has been erected, though the latter is not yet in operation. Other mine buildings and a town are being planned. The mine will produce in the neighborhood of 2,500 tons daily.

New companies organized in West Virginia during August had an aggregate capitalization of \$260,000. They were the following: Crandall Mining Co., of Altman, capitalized at \$50,000; Duffy Brothers Coal Co., of McMechen, capitalized at \$10,000; Manufacturers Gas Coal Co., of Wellsburg, capitalized at \$50,000; Rogers Elkhorn Coal Co., of Virgie, Ky., capitalized at \$150,000.

The Crystal Block Coal & Coke Co. has increased its total authorized capital stock from \$500,000 to \$700,000. Other concerns increasing their capitalization include The Peerless Smokeless Smithing Co., from \$100,000 to \$500,000; New Howard Coal Co., from \$300,000 to \$400,000; Cardiff-Pocahontas Coal Co., from \$100,000 to \$150,000; The Peerless Smokeless Smithing Company has changed its name to the Peerless Fuel Co.

Roda No. 1 team of the Stonega Coal & Coke Co., tied with the Derby No. 2 team of the same company, won by a small margin in the play-off at the sixth annual first-aid meet of the Virginia Coal Operators Association on Sept. 20. The Roda team has been victorious for two years and has enabled the Stonega company to win the association cup three times in the last six years. Twenty-nine teams were entered. The American Red Cross, U. S. Bureau of Mines and the National Safety Council co-operated with the Virginia association in holding the meet.

## WYOMING

W. C. Alden, of the U. S. Geological Survey, has completed his summer's geological work in Wyoming.

Mine exhaustion and operating troubles in Union Pacific Coal Co. coal lands in the Cumberland region have caused the company to employ A. R. Schulz, a former government geologist, to prospect the Cumberland region in an effort to locate deposits which will enable the company to open new mines without abandoning that district.

According to a recent announcement, the Sheridan-Wyoming Coal Co. will operate its own property in the future. D. P. B. Marshall, attorney for the firm, announced the cancellation of the company's contract with the Peabody Coal Co. for operating and selling. Harry N. Taylor, of New York City, will continue as president of the Sheridan-Wyoming company. He has held the office for the last year, succeeding Peter Kooi, of Sheridan. The Sheridan-Wyoming company will now organize its own operating and sales departments, and will hold in the field a great majority of the local personnel formerly employed by the Peabody. Edward Botmley, who has been division super-

intendent in charge of operations in this field ever since the consolidation in 1920, has been invited to continue as general superintendent in charge of operations for the Sheridan-Wyoming company.

## CANADA

Dr. Charles Camsell, chairman of the Dominion Fuel Board, states that only from 25 to 50 per cent of the consumers of domestic fuel who last year bought their winter's requirements during the summer have done so this year, and fears that this condition will disturb prices and cause considerable inconvenience.

At a special meeting of the preferred shareholders of the Dominion Coal Co. in Montreal on Sept. 23, a mortgage of \$15,000,000 on the company's property was authorized. President Roy N. Wolvin announced that a reserve fund would be created to be drawn upon for the payment of dividends in years when current earnings might be insufficient for the purpose.

J. E. McLurg, vice-president of the British Empire Steel Corporation, states that it is the intention of the company to send three or four of the mine managers of the Dominion Coal Co. on an educational trip through the coal districts of the United States.

The Coal Dealers' Association of Regina, Alta., states that owing to the protracted miners' strike there is serious danger of a coal shortage in that city. They have stocks on hand sufficient to last for only five or six days of cold weather and no plans are being made to relieve the situation by bringing coal from the East.

The Scranton coal mine, situated northwest of Drumheller, Alberta, was re-opened on Sept. 15, the miners accepting last year's contract. The output of 100 tons daily will be rapidly increased. Two other large mines are preparing to sign up with their men. John A. Henderson, of Winnipeg, part owner of the Gem mine, in Northern Alberta, states that there is more coal coming to Winnipeg from Alberta than is required to meet the present demands of householders who have been holding back orders on account of fine weather. All the mines west and south of Edmonton are working with non-union labor.

## Industrial Notes

F. C. Ackerman, formerly fuel supervisor for the Baltimore & Ohio R.R. at Wheeling, W. Va., has severed his connections with that company and is now representing the Hulbert Oil & Grease Co., of Philadelphia, in the Wheeling district.

Martin G. Sperzel was elected a director and the vice-president of the **Royersford Foundry & Machine Co.**, Royersford, Pa., at the regular Board Meeting held Sept. 10. He succeeds H. R. Will, who has retired from the company. Mr. Sperzel also will assume new duties as the company's general manager. He will continue, however, to be in charge of all sales including machine tools, punch and shear machines, and tumbling barrels, which heretofore have been directed from the home office at Royersford, Pa. Mr. Sperzel will be, as at present, in the Philadelphia office of the company, at 52 North Fifth Street.

## Traffic

### Ohio Coal Company Withdraws Rate Protest

The Ohio Collieries Co., Toledo, Ohio, has dismissed its protest pending before the state Public Utilities Commission against the coal and freight rates of the Hocking Valley R.R. on shipments from the Hocking and Pomeroy district to Columbus.

The case had been set for a second hearing by the commission for Sept. 24. The protest contended that the rate, \$1.26 per ton, was unjust and discriminatory as compared to the rates on West Virginia coal. One hearing already had been held at which the coal company produced evidence to substantiate its claim that rates should be lowered.

Governor Donahey a few days ago directed the Attorney General's department to take action before the Utilities Commission in an effort to have this inequality in rates adjusted for the benefit of Ohio miners and operators.

### Dealers to Combat Higher Rates From Illinois and Indiana

'Coal dealers' organizations and other consuming interests are organizing throughout the Northwest to combat the proposed increase in rates on coal from Illinois and Indiana to Wisconsin, Minnesota and the Dakotas. These rates were ordered originally in the Lake Dock cases decision, but were suspended in so far as they applied to central and northern Illinois and to Indiana. They are now in effect on coal from southern Illinois, however. The suspension period ends Jan. 8 and hearings no doubt will be held before then.

### Idaho Coal Rates Reduced

Lower freight rates on coal from the Brown Bear mine of the Teton Coal Co. to all points on the Oregon Short Line in Idaho were filed Sept. 18 with the State Public Utilities Commission by the railroad company.

The new tariff, prepared in compliance with the commission's order of Aug. 23, is made retroactive; its effective date being that of the order.

Virtually, the new rates are those compiled by Samuel N. Newton, rate expert of the commission, as alternatives for rates proposed in a tariff filed by the railroad company on July 12, which was suspended and made the subject of a commission hearing held at Pocatello on Aug. 4.

The original tariff was held to be discriminatory because it contained rates higher per ton-mile than those in effect for coal hauled from Wyoming and Utah fields. As amended, the rates were lowered from 5c. to \$1.70 a ton in nearly all points in the state.

The tariff is the latest step in the experiment, marked by an extended contest before the Utilities Commission, by H. F. Samuels, Progressive nominee for Governor, and his associates, Robert H. Harlin and Carl A. Reichert, to bring the old coal prop-

erties of the Teton valley into successful operation again. After commission hearings which resulted in an order requiring the Oregon Short Line to repair its tracks from Talbott Junction to the Brown Bear mine, an agreement was reached between the parties, the tracks were repaired and shipments of coal began on July 7.

## Obituary

**James M. McVey**, president of the Cadel Ridge Coal Co., and a well-known operator of Fayette County, met instant death on the night of Sept. 19 when an automobile he was driving plunged down a steep embankment near East Bank, W. Va. Mr. McVey, who was 44 years old, had taken an active part in politics and was elected on the Republican ticket as a member of the Legislature from Fayette County, serving at the session of 1919. Succeeding him in that office was his brother-in-law, H. T. Lyttleton, who met death in the same way about two years ago near Glen Jean. At that time Mr. McVey was in the machine but escaped with a few bruises. The funeral was held at Charleston.

**I. B. Parsons**, 75, a pioneer of the Birmingham (Ala.) district, and for many years associated with various coal companies in exploiting coal lands in the vicinity of Birmingham, died Sept. 14 at a local infirmary after a brief illness. Mr. Parsons was born at Adger, Ala., and went to Birmingham when he was about 10 years old. Beside his coal-land work, he served a number of years as a deputy for the county. He leaves two sons and five daughters.

**Frederick Rice Buell**, formerly Lehigh Valley coal agent in Milwaukee, died Sept. 12 in the suburbs of Cleveland. He was born in Geneseo, N. Y., 70 years ago and was for some years, as a young man, connected with the wholesale anthracite business of Andrew Langdon in Buffalo. He had a diversified career, going to the Klondike in the gold rush there and once owning a ranch in Idaho. He was educated in Buffalo and the University of Michigan. His father, Frederick Buell, was Collector of the Port of Buffalo and his mother was a daughter of the Rev. Charles Backus Storrs, founder and first president of Western Reserve University, Cleveland. He left no descendants.

## Coming Meetings

**Alabama Mining Institute.** Annual meeting, Oct. 7, Hotel Hillman, Birmingham, Ala. Secretary, James L. Davidson, American Trust & Savings Bank Bldg., Birmingham, Ala.

**Illinois Coal Operators' Association.** Annual meeting, Oct. 7, Chicago, Ill. Secretary, C. E. McLaughlin, Fisher Bldg., Chicago, Ill.

**National Coal Association.** Board of Directors' meeting, 9:30 a.m. Oct. 10, Washington Hotel, Washington, D. C. Open to association members and those interested. Executive Secretary, H. L. Gandy, Washington, D. C.

**American Institute of Mining and Metallurgical Engineers.** Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

**American Institute of Electrical Engineers.** Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

**American Gas Association.** Sixth annual convention and exhibition, Steel Pier, Atlantic City, N. J., Oct. 13-17. Secretary, Alexander Forward, 342 Madison Ave., New York City.

**Canadian Institute of Mining and Metallurgy.** Sixth annual Western Meeting, Oct. 16-18, Blairmore, Alta. Can. Secretary, Moses Johnson, Blairmore, Alta., Can.

**Illinois Mining Institute.** Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

**West Virginia Coal Mining Institute.** Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

**Coal Mining Institute of America.** Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 909 Chamber of Commerce Bldg., Pittsburgh, Pa.

## New Equipment

### Safe Motor-Starting Switch

A safety switch suitable for use with small motors and under conditions where it is desirable to interrupt currents quickly has been placed on the market by the Trumbull Electric Manufacturing Co., Plainville, Conn. The fuse block is mounted over the switch base so that the fuses are readily accessible. Line leads can be brought in either at the top or bottom of the switch. The switch is provided with a

### Quick Make-and-Break Switch

Switches like these are suitable for starting small motors. The quick rupture of the circuit is accomplished by a spring attached to the operating handle.

quick make-and-break device and an interlock.

The construction is of the "dead-front" type, a shield being used to cover the line terminals. The switches are furnished fused or unfused two-pole or three-pole for 250-volt service, but 440-volt and 550-volt two-pole and three-pole switches will soon be placed on the market.

### Power Drive for Die Stocks

Undoubtedly every man who has had the experience of pulling on a die stock knows of other jobs he would rather do. It's a back-breaking proposition. The large power pipe-threading machines used today are back savers and are great things for shop use; but what of a small, compact, power outfit capable of threading all sizes of pipe used generally in every-day work and as easily conveyed from job to job as a hand tool!

To meet the requirements of a tool of this character the Oster Manufacturing Co., Cleveland, Ohio, has brought out the machine illustrated herewith. A clear conception of the simplicity and compactness of this little unit may be gained from a study of the illustration presented.

It has both the qualifications desired

### A Handy Machine for Use Where Much Piping Is Done

Pipe may be threaded, cut and fitted with this little power unit. It is portable and operates from the ordinary electric-light circuit.

—portability and the capacity for handling all sizes of pipes used mostly by anyone having pipe threading to do. It weighs but little over 200 lb. and may be conveniently handled by two men. The machine being designed to drive the No. 104½ Oster bulldog die stock gives it a range covering all sizes of pipe from ¼ to 2 in. inclusive. Its length over all is 2 ft. 11 in., width, 1 ft. 2 in.; height, 1 ft. 8 in.

A ½-hp. motor geared to the driving arms furnishes ample power to thread all sizes within the range of the machine. The driving arms maintain a no-load speed of 9 r.p.m. and approximately 8 r.p.m. under a load. The machine is not a rapid production outfit but it will keep two or three good men hustling to fit up the pipe it will thread. Running the machine from an ordinary electric-light socket eliminates the necessity of installing extra wiring. A built-in scroll chuck and auxiliary centering guide are two desirable features, no extra vise being required. Both the chuck and the guide are self-centering and self-locking.

Due to the fact that the gears are completely enclosed and running in oil, the machine operates with very little noise and wear.

The machine as a whole is claimed to be very durable, built to stand the everyday hard use over the ordinary business lifetime. The driving arms which are necessarily strong are of malleable iron. The chuck jaws and guides being subjected to much wear, are drop-forged steel, case hardened. The machine was originally intended to be used for driving the bull dog die stock. However, it was equally efficient in driving a hand cutter.

The cutter is placed on the pipe in much the same fashion as it is when about to be cut off by hand. The handle rests against one of the driving arms and the machine revolves it. All the operator does is to tighten it on every revolution. The machine later proved its ability to turn up fittings as well. The elbow coupling or tee is started by hand, one or two turns are given, a wrench is placed on it, and the driving arms do the rest. When the fitting is tight the operator simply snaps the switch.

### Starter for High Voltage Induction Motors

An automatic high-voltage compensator has just been placed on the market by the Electric Controller & Manufacturing Co., Cleveland. This compensator is built for voltages as high as 2,500 and below. It is pushbutton operated and entirely automatic. With the exception of the overload panel, which is mounted on the top of the tank, the compensator is entirely submerged in oil and the tank is so designed that it is dustproof, weatherproof, vaporproof and fireproof. The compensator can be installed either indoors or outdoors.

A pushbutton supplied by energy from a low-voltage circuit which is taken from an independent transformer is so arranged that there is no danger

of the operator ever coming into contact with the high-voltage circuit. Because the starting transformers and the operating mechanism are entirely submerged in oil and automatically operated, all possibility of explosions or high-voltage flashes is removed.

This automatic compensator is so designed that continuous torque is ap-

### No Moisture or Dust Can Get In This Automatic Compensator

Built like a transformer and sealed against moisture and dust, this unit is made safe for service anywhere.

plied to the motor from the time the pushbutton is pressed until the motor has been brought up to full speed. Operation of the starting switch causes the motor to be started under reduced voltage.

### Contactors and Starting Transformers Submerged in Oil

All the current-carrying and transforming elements of this starter are operated in oil. A separate transformer supplies current to a pushbutton switch used for starting and stopping the motor. After the motor has reached the proper and safe speed it is automatically thrown across the line.

## Half Truths Are Misrepresentations

SECRETARY DAVIS at the National Safety Council meeting in Louisville called for facts about accidents and suggested that the Department of Labor was going to ascertain them, if Congress would support that development of the department's activities.

We have consistently contended that the facts about coal mining were misleading because they were not compared with facts regarding other industries. Now it appears that other industries are to come out into the light so that a comparison will be possible. It will no longer be so easy to condemn the coal industry simply because it has a record and the others no record at all. The coal industry feels glad that investigators are sharpening their pencils to keep track of other industries, confident that when the records are disclosed it will be realized that "when a man's a miner" he is not unduly prone to death.

There are other ways in which coal is being measured, and the measurement is unfair because it is not comparative. Perhaps after a while such measurements will be applied generally and it will then be found, we believe, that coal mining, though by no means clean of fault, does not compare unfavorably with other activities. Should the comparison, however, prove unfavorable the industry will be spurred even more than in the past to a house cleaning.

## Screenings! Screenings!

THE ANNUAL futile struggle to sweep back the resistless tide of low price screenings is on. In some of the Midwest mining fields where the market price of screenings dropped enough to absorb all the seasonal increases on domestic sizes, operators are determinedly piling fine coal on the ground. And believe them, they are going to hold those screenings there if necessary until it's 32 above zero in Hades before they give that coal away to the patiently waiting big steam buyers. And so on and so forth. It is pitiful to hear them talk.

The truth of the matter is that storage at mines may raise the price of those screenings a shade—even enough, here and there, to cover storage losses and the cost of putting the coal down and picking it up again—but storage is no permanent cure for the screenings problem. The real cure lies in coking that fine coal. Some day the right process of low-temperature distillation will be evolved, economical types of ovens will be built. Then fine coal—if not even the whole mine output—will yield at least a part of its byproduct content and eventually be sold as good coke.

That day may not be far distant. Out of the extensive trail-blazing now going on somebody is going to chart the right course. One Illinois coal mining company is spending a quarter of a million dollars on

experimentation in low-temperature distillation. With rare vision, and an even rarer willingness to spend money, these people realize that the mine operator stands to benefit first from the development of such a process and, therefore, should be first to know the art.

It is fitting that Illinois get seriously down to business because its proportion of screenings has increased from 19 to 48 per cent of the state's total output from 1900 to 1923, and the present annual loss to the state is from \$10,000,000 to \$12,000,000, if we accept the estimate of that skilled statistician Dr. F. C. Honnold. Considerable reduction in the proportion of screenings can be effected by improved blasting—possibly by the complete abolition of explosives—but low-temperature coking is the true solution of the screenings problem.

## Working in the Dark

ELECTRICAL equipment plays such an important part in the successful operation of a mine nowadays that we wonder why so many mining officials are tardy in recognizing this fact.

Coal companies are of several kinds in this respect. There is the company that has an electrical engineering department which functions as such. Another company occasionally employs a consulting electrical engineer. A third type hires a chief electrician and lets it go at that, while a fourth is the company that just drifts along.

The ideal electrical organization is no doubt the one that plans and supervises the installation, use, and repair of all electrical apparatus belonging to the company. Such an organization is always on the job and continually sensitive of the changes and progress to be made by the company. Many appreciable savings can be effected by such a unit because nothing can occur within its scope of supervision without receiving proper attention.

Any company employing a consulting electrical engineer should not only use his services for particular jobs but have him continually in touch with all electrical details of the company. Only by a complete understanding of the various problems of a mine can a consulting engineer do his best. If an engineer is only temporarily employed the equipment he installs may never function as successfully or economically as was intended. He should remain on the job and direct its operation.

Too many companies are prone to fool themselves regarding their electrical organization. Self deception may be great sport for some people, but at home is a poor place to begin to fool. An electrical engineer traveling through some sections of the mining field would hate to be called an electrical engineer after he had seen some of the men who have been handed this title by their employers.

Those companies not having someone to look after their electrical apparatus are either small or some peculiar conditions are keeping them from bankruptcy. An adequate conception of the importance of electrically operated machinery by the managing officials will quickly make them realize that the day has passed when they can operate without knowing what is happening to their electrical energy or what is causing delays and high maintenance costs.

### Possibilities of Stainless Steel

ONE OF THE useful metal alloys to make its appearance within recent years is that known as "stainless steel." At first to most people this metal appeared to possess possibilities only in the direction of domestic utensils, cutlery and the like. Its production and use, however, has now progressed to the point where it would seem to be adapted to a far wider field of industrial usefulness.

Steel of this kind is stainless because it resists both acid and corrosion. This characteristic renders the material suited for many uses to which ordinary steel is but poorly adapted. Of course, only the test of time and use can establish the adaptability of any metal to engineering purposes and the utility of any product is determined by balancing its cost against the service rendered.

At the present time, however, it would appear that stainless steel might find a place in the coal industry as shaker jackets, chute linings, jig linings, pump linings, as pipe for conveying acidulous water and in short wherever a forged or rolled acid-resisting metal is now desirable. It might be interesting to ascertain also how a steam power boiler built of this alloy or its close relative, rustless iron or chrome iron, would endure when fed with acidulous mine water. If its performance and life were satisfactory the water problem of many a mine now experiencing difficulties of this kind might be permanently solved.

### The Humbug Harvest

AUTUMN is pre-eminently the season of harvest. But the harvests of grain and fruit are not the only ones that come to maturity in the Fall. Almost every autumn brings forth its crop of "fuel savers." No sooner do leaves begin to accumulate on the lawn than the good man of the house begins to receive "literature" setting forth in glowing terms the advantages, pecuniary and laborwise, of installing this or that device on the furnace door, the check damper, the smoke pipe leading to the chimney, or of treating the fuel or the ashes with some marvelous chemical that simultaneously aids combustion and conserves the purse, the back and the commandments.

Now it is not the intention here to utterly condemn all of these devices, *en masse*, as unmitigated fakes and humbugs. Some of them if properly installed and handled may give some degree of economy. As a rule, however, an equal economy could be secured by proper manipulation of the furnace itself.

Taking them by and large the "fuel savers" that make their appearance with the first frost and fade away about the first of March, are of three general types: Chemicals, devices placed between the furnace

and the chimney or within the chimney and devices that admit air above the fuel bed.

Most chemicals sold in powder or crystal form, to be dissolved in water and sprinkled on the fuel to promote its combustion or "make it go farther," or to render possible the burning of ashes, have little or no real value. Common salt added to coal or coke in the proper amount will change the color of the flame imparting a characteristic yellow tint. Copper or its salts gives an equally characteristic blue tinge. Such chemicals may deceive the observer but hardly aid combustion. Sodium or potassium nitrates and in general, chemicals that liberate oxygen on the application of heat may aid combustion but are expensive and consequently are sedulously avoided by the concoctors of "fuel savers."

Devices placed between the furnace and the chimney or within the chimney itself usually operate on the idea that lowering the chimney temperature prevents heat loss or rather lessens the quantity of heat that "goes up the flue." While it is quite true that admitting cold air into the smoke pipe or chimney lowers the temperature of the chimney gases, it is not true that this process accomplishes any desirable result. In fact it may seriously reduce the draft and decrease the rapidity of combustion on the furnace grate.

Devices that admit air immediately above the fire come on the border line of usefulness. It is a fact that certain fuels require the admission of air above the fire during the coking process if perfect combustion is to be secured. In order to be effective, however, this air should be thoroughly mixed with the gases arising from the fuel bed before these gases come in contact with the comparatively cold metal surfaces of the furnace. Practically all furnaces are fitted with a draft in the fuel door for this express purpose. This draft is masked by a perforated baffle plate intended not only to prevent the fuel door from warping but also to heat the air admitted above the fire and to introduce it into the combustion chamber in a series of small jets or streams so that it will mix thoroughly with any combustible gases that may be present.

Ordinarily the householder forgets all about this little draft in his furnace door and the function it is supposed to perform. The device in question in effect substitutes some other form of air and gas mixing device and keeps the draft permanently open. It may or may not perform a desirable function depending upon the volatile content of the coal burned, the desired rapidity of combustion and other factors.

Nothing that has been here said is intended as casting any reflection upon various electrical stokers intended to render available to the householder the finer grades or steam sizes of anthracite. Nor is aspersion cast upon many other devices such as thermostatic furnace controls or various chimney caps or cowls that increase the draft. Many of these are designed on scientific principles and really accomplish economic results. But it has been rather the endeavor herein to point out that there are various and sundry fly-by-night, catch-penny schemes to which no honest coal producer or dealer can afford to lend his sanction.

IN RUSSIA loose-tongued enemies of the government in the streets are silenced forever in the coal mines by the dreaded Tcheka. In America we can't even check a few that are already in the mines.

Testing Battery Cells

## How to Save Power and Thus Reduce Maintenance And Operating Costs of Mine Machinery

By Reducing Power Used Motors Are Saved from Overloading—Watch Operation Through Power Consumption—Machine Bits of Irregular or of Excessive Length Waste Power—Frequent Sharpening Less Desirable Than Correct Shaping and Tempering

By W. H. RUSSELL  
Farmington, Ill.

**T**HOUGH the cost of electric power used in mining coal heretofore has not been a large item, in comparison with that for labor, changes in the system of mining seem likely to increase the power used. This will eventually mean that it will be necessary to have facilities for separating the power cost for each class of service just as the cost of labor is now separated. This is the only practical means of detecting and locating leaks so that they may be stopped. Such a system may be quite expensive in some cases and in others cheap. Where power for cutting and haulage operations is supplied from separate feeders, it is a simple matter to meter their requirements.

With direct-current systems supplied by alternating-current converting apparatus, it must be remembered that the total direct-current power supplied by a converter or motor-generator set will not equal the alternating-current power supplied to the converting equipment, yet it is for the alternating-current power that payment must be made. The losses, however, can be charged in proper proportion to the power used as recorded by the direct-current meters.

This method has often disclosed a serious loss caused by running a large motor-generator set to supply direct-current power for a small pump during the night shift. Sometimes it requires more power to operate the motor-generator set than it does to run the pump. Such a loss may amount to a considerable sum of money in the course of a year, besides the wear on the motor-generator set.

NOTE—By keeping tabs on the current consumed by apparatus, as shown in the headpiece, correct conclusions can be made as to the condition of the equipment. Load charts will tell when a motor is overloaded and quickly show whether it is earning or saving the money expected.

One of the principal reasons for keeping separate records of the cost of power for different purposes is that many things can happen to mining machines, locomotives and other machinery which will cause them to be wasteful of power even when they appear to be working satisfactorily and efficiently.

Wasted power may seem to be an insignificant subject to some who have never investigated it, but it is a fact that some of the simplest things may be causing leaks which amount directly or indirectly to thousands of dollars annually. For instance, it was decided a few years ago that the cutter chains on our mining machines were not properly arranged and were the cause of undue wear on all parts of the machines. After some experimenting we decided that a certain arrangement would give the best results and all of the chains were rearranged accordingly and that without the use of any new parts except rivets.

The immediate results were an increase of from 15 to 20 per cent in the work accomplished by the machines and a noticeable reduction in the heating of the motor and cable. From this example it can be seen that a reduction in the power required by the machines will make savings by decreasing the wear and strain on every part of the machine, but the saving of power is in itself well worth while.

After using this new arrangement of the chain for a month, we found that the power consumption for coal cutting had dropped from 1.33 kw.-hr. per ton to 1.09 kw.-hr. per ton. After several years use of the same chain arrangement it has been found that the power consumption for all of the machines, both shortwall and breast types, varies from 1.04 to 1.2 kw.-hr. per ton whereas for all of the time previous

to the adoption of this chain arrangement, beginning when the machines were new, the power consumption varied from 1.1 to 1.52 kw.-hr. per ton, the average saving being about 0.6c. per ton. The power consumption for two typical years before and after this change expressed in cents per ton is shown in Fig. 1. These results were all obtained from machines operated in a 4-ft. seam and include the power-conversion losses from alternating to direct current and transmission to the machines.

#### KEEP CLOSE WATCH OF POWER CONSUMPTION

It is not a difficult matter to measure the power used for various purposes, but it probably is impossible to estimate accurately the indirect savings that can be effected by keeping watch of the power consumption and maintaining it as low as possible. Unfortunately the usual system of mining coal does not permit close supervision of either machinery or men, but a good check on the performance of machinery can be kept by a constant comparison of the cost of power with production.

Not all the defects which are revealed by a close watch of power consumption are mechanical or electrical—the human element is a big factor. Machine runners

Fig. 1—Results Obtained by Rearranging Cutter Chains

Improper adjustments of chains on coal-cutting machines quickly increase the amount of power required. Delays and the careless repair of cutter bits also increase operating costs.

as a rule do not realize that if they do not set their bits properly they may increase the load on their machine as much as 25 or even over 50 per cent. If you have ever used a dull saw with teeth improperly set and then used it again after it had been sharpened and accurately set, you can realize what can be done to a mining machine by setting the bits at all lengths so that the long ones are immediately dulled. The first indication of poor results is in the power consumption and the last, perhaps, in the junk heap.

It must be remembered also that the bits may be set perfectly even and still cause unnecessary load by setting them a little too long; if they are set so as to cut a 6-in. kerf when a 5-in. kerf is enough, the power used in actually cutting the coal is increased and the quantity of cuttings is increased 20 per cent.

#### PROPERLY SHARPENED BITS EFFECT SAVINGS

The sharpening of bits is an important matter but only too often is it neglected. It seems as though the sole object of some bit-sharpening departments is to turn out as large a number of bits as possible. A little intelligent inspection will often disclose the fact that half the same number of bits, if properly sharp-

ened and tempered, would do more work with less power and effect many savings.

Here again the human element should be considered; the average machine runner is more likely to change the bits in his machine when necessary, if he has a good supply which he knows will fit the chain without much hammering. If he can do a fair quantity of work after he gets them and does not have to hunt all over for a box of bits which he knows he will have trouble in setting into his chain, he will take better care of his machine. If he breaks the points off half of them driving them in and afterwards sees some of the others break off the instant they strike the coal, he soon cares little about his work. If the latter condition prevails he will be sorely tempted to put off changing bits as long as possible.

The sharpening and tempering of bits is a matter which deserves no little attention and, if the cutting is extremely hard, the proper attention to sharpening, tempering, delivering, and setting of bits will pay big returns. Once the proper system is well established and understood, the satisfaction resulting to everybody concerned is usually enough to keep it going with but little attention.

It has been found that the practice of checking up the power consumption of apparatus has been the means of discovering numerous wastes of power, some of which are important because of power losses and others because of damage to equipment by bad operating practices, such as starting locomotives in parallel, operating motors on resistance points, or running on grades with the motors in parallel when better results could be obtained with the motors in series. Mining machines are often geared too high, and this makes it necessary to run on resistance points with much waste of power and damage to the rheostat. In the opinion of some engineers this is a rather common fault of gathering locomotives. It is quite possible that there are some cases where heavy grades predominate and a slow-speed locomotive would be better for main haulage service.

#### VOLTAGE DROP WASTES POWER AND CAUSES DAMAGE

Voltage drop is a common form of wasted power. It results in serious damage to every electrical part of the system, not to mention the slowing up of production. Excessive voltage drop is usually the result of ignorance. It is my opinion that the voltage drop should not be allowed to exceed 10 per cent, but many will argue that the interest and other expense of sufficient copper to keep it at that value or less is more than the saving that can be effected. This would be rather a hard thing to prove, but it is certain that money invested in copper is much more easily converted into dollars and cents than wasted heat energy and roasted field coils and armatures.

The damage, unnecessary expense, and a long train of other evils, which are the result of allowing power wastes to continue, cost more than the power which is wasted. Power consumption is such a good indicator of production that it seems as though every possible advantage should be taken to know how much coal every kilowatt-hour produces and what part of every kilowatt-hour purchased or generated is wasted in roasting some perfectly good motor because it is dragging around a worn-out cutter chain or because somebody installed an expensive compressed-terminal rail bond with a hammer instead of with a bond compressor.

# Alabama Coal Washing and Cleaning Practice Helps Make Good Metallurgical Coke\*

Beds Carry so Much Extraneous Matter That Cleaning Is Necessary—Dirt Mostly Confined to Medium Sized Mine Product—Small Coal May Be Shunted Past Jigs—Sludge Must Be Recovered

BY H. S. GEISMER  
Birmingham, Ala.

**B**ACK in 1896 H. H. Campbell stated that: "The Birmingham district in Alabama has certain great advantages for there are few places in the world where fuel and ore are so near together, although, unfortunately, both are of inferior quality; the ore being low in iron and high in phosphorus and the coal giving a weak and impure coke."

This statement could not have been questioned in 1894, but by 1896 several Robinson-Ramsay washers had been put into operation and weak and impure coke was a thing of the past.

The Warrior coal field of Alabama contains six beds that yield coking coal of excellent quality. In descending order, these are: The Brookwood, Milldale, Pfatt, America, Mary Lee, and Black Creek. In each of these, however, occur bands of rock and bone; and while some of the impurity present can be separated and gobbled by the miner, much of it must be loaded out with the coal. Consequently, unless the coal is washed it will yield a coke of varying ash and sulphur content quite unsatisfactory for blast furnace use. At present, the Gulf States Steel Co. is producing run-of-mine coal at its Virginia mine, from the America seam, that is sufficiently uniform and low in ash to permit of coking without washing, but this is the only exception to the above statement.

At the present time two new systems of coal cleaning are attracting attention throughout the United States—the air or dry-cleaning process and the Chance sand-liquid method. Neither of these has been tested in Alabama but with these two exceptions all the methods used for cleaning bituminous coal have been largely brought to perfection in this state.

## TWO-COMPARTMENT JIGS USED ON COKING COAL

In recent years, practically all of the plants designed to produce coking coal have used two- and three-compartment jigs, while the companies making washed coal for commercial purposes favor single-compartment machines. Experience with Alabama coals has demonstrated that there is little difference in the quality of the washed coal produced on the different jigs if they are intelligently operated; there is, however, a wide variation in the amount of water required and the percentage of coal lost in the refuse.

When the first washers were built in Alabama, coal costs were low and the land surrounding the mines was owned principally by the operating companies. Fine coal was considered a necessary part of the sludge, and was allowed to find its way to the nearest stream.

Increasing coal costs made it advisable to recover the fines and damage suits, instituted by the farmers upon whose land the sludge was deposited, made it necessary to retain the sludge at the plant.

## THREE METHODS OF RECOVERING FINES

At present, three methods are used for recovering the fine coal from the sludge and for clarifying the sludge-carrying water. These include: (1) Long settling or clearing tanks with slowly moving conveyors that drag the fines that settle along the bottom to the discharge end. This is the most common method, but where large capacities are treated it often requires all-night operation of the conveyor to recover the fines that have accumulated during an 8-hr. shift. It also has certain other drawbacks.

2. All the overflow water from the washed-coal settling tank (this water contains all the sludge) may be pumped to an elevated conical tank. The water is recovered from the top of the tank and flows back to the sump. The fine material is drawn off at regular intervals from the bottom of the tank and carried, by a conveyor, to the top of the washed-coal bin. The conical tank is far superior to the long horizontal tank, and there is nothing connected with it to get out of order.

3. To date, two installations of Dorr thickeners are to be found in Alabama; one is at the Palos plant of the Republic Iron & Steel Co., where coking coal is produced, and the other at the No. 2 Overton plant of the Alabama Fuel & Iron Co., which produces steam coal. The fines recovered by the Dorr thickener at Overton have no commercial value, as they run high in rash and fireclay, but as the washing plant is located near a large river it was considered advisable to prevent the sludge being carried into this stream.

At all the Alabama operations where coking coal is produced, the sludge consists of water, pure fine coal, and fine impurities. The percentage of impurities, however, is not large and it is neither necessary nor profitable to separate it from the fine coal. At some of the operations in the non-coking fields, the sludge contains a large percentage of rash and fireclay. In such cases the material passing 20-mesh is worthless and no attempt is made to recover it.

## STANDARD SIZED SCREENS HAVE BEEN ADOPTED

Alabama plants producing steam or commercial fuel almost invariably screen all the coal as it comes from the mine and wash only that portion that passes through the screen perforations. Generally these are 2-in., but occasionally 3-in. perforations are found. Such plants do not require crushers. To meet the growing demand for stoker coal, some of the commercial mines may

\*Abstract of paper entitled "Coal Washing Practice in Alabama," to be presented before a meeting of the American Institute of Mining and Metallurgical Engineers, Birmingham, Ala., Oct. 13 to 15, 1924.

decide in the near future to crush their entire output and sell it in this condition.

Plants producing coking coal almost invariably crush and wash their entire output. At two large modern plants, however, the coal as it comes from the crushers is screened and the fines bypassed, only the coarser product being washed.

Two-roll crushers generally have been used for crushing. Several hammer crushers were installed in the early days but they produced too large a percentage of fines and complicated the sludge problem. Of late years, Bradford breakers have been installed at most of the large operations replacing crushers. At one plant in particular, one of these machines has entirely replaced crushers and has increased appreciably the capacity of the washer, as the breaker serves as a preparatory cleaner and relieves the jigs of some of their work.

At the mines where the entire output is washed, the coal is generally crushed to pass through a  $\frac{3}{4}$ -in. circular opening; this size gives excellent results on plunger jigs of the Elmore or Faust type. With the Stewart and Montgomery jigs, the size of the coal treated has little bearing on the quality of the washed coal produced; in fact, a feed of mixed sizes, from 2 $\frac{1}{2}$ -in. down, gives excellent results. Sizing before jigging as an aid to washing is not attempted at any plant in Alabama; sizing the coal to permit of bypassing the fines has quite a different object.

Because of the large percentage of slate and bone found in most Alabama coals, officials in charge of properties producing washed coal for coking purposes early realized the necessity of placing chemists at the coal washers to keep accurate record on the results obtained. It was soon found that these men were not only able to improve the quality of the washed product and to keep it uniform but also to reduce the cost. Their tests showed whether an excessive amount of coal was being lost in the refuse (this always indicated something wrong with one or more of the jigs). Such a condition being quickly noticed, could be remedied before any large loss resulted. Operating a modern coal washer without a chemist is like running a modern power plant without recording gages.

#### WASHERY BUILDINGS ARE OF PERMANENT NATURE

All buildings around coal mines formerly were constructed of wood and the first coal washers were made of the same material. Gradually steel and concrete replaced wood for all mine buildings including coal washers. There is much difference of opinion as to whether concrete, cast iron, or structural steel is best suited for jig tanks and all three have their advocates. Steel plates are not satisfactory if the water being circulated in the jigs is corrosive; if it is not corrosive fairly heavy plates have been found satisfactory. In the modern plants fireproof construction is used throughout.

The four large iron-producing companies of the Birmingham district have done much experimenting with coal washers and data covering one washing plant of each company has been furnished.

The Woodward Iron Co. coal washer at the Woodward byproduct plant handles Pratt seam coal from the company's mines at Dolomite and Mulga. All the raw coal goes through Bradford breakers and the material rejected by them is carried to the refuse bin. The material passing the breaker perforations is delivered to a

battery of Hummer screens. The material passing through the screens ( $\frac{1}{8}$  x  $\frac{1}{2}$ -in. slots) bypasses the jigs and is taken directly to the washed-coal conveyor. Approximately 30 per cent of the total run-of-mine coal is bypassed in this manner.

The jig plant consists of four three-cell Faust jigs. Although the primary jigs are of the three-compartment

Jig Floor, Risco Coal Washery

This plant, which is the property of the Republic Iron & Steel Co., treats coking coal. Much of the development work that has made modern coal washing equipment effective has been done in the Birmingham field of Alabama.

ment type, a secondary product is not produced, the refuse from the third cells and the third hutch is handled in a battery of rewash jigs and the resulting washed product goes to the primary washed-coal bin. Two cone settling tanks have been installed here. As this plant is located within a few hundred feet of the byproduct ovens, the coal is dewatered in three Elmore dryers.

Figures showing the results from this plant have been furnished by the Operating Department of the Woodward Iron Co. and are set forth in Table I.

Table I—Results Obtained at the Woodward Byproduct Plant

	Volatile Matter, Per Cent.	Fixed Carbon, Per Cent.	Ash, Per Cent.
Raw coal (coal sent to Bradford breakers).....	26.77	63.52	9.91
Bypass coal (coal from breakers passing through $\frac{3}{4}$ x $\frac{1}{2}$ in. slot, going to coal bin without washing).....	28.03	66.43	5.54
Coal to jigs (coal from breaker passing over $\frac{3}{4}$ x $\frac{1}{2}$ in. screen).....	25.96	62.15	11.89
Coal from jigs (average from 4 Faust jigs for year ending May 1, 1924).....			5.52
Coal from rewash jigs (average for year ending May 1, 1924).....			9.46
Washed coal (a mixture from all jigs and bypass coal).....	27.95	66.05	6.00

Refuse for the year, ending May 1, 1924, contained 3.21 per cent float; the ash in the float amounted to 6.58 per cent. The specific gravity of coal is taken as 1.37. The result of a screen test on coal from elevators (coal from all jigs) follows:

On 0.747-in. opening— 5.9 per cent.  
 On 0.525-in. opening— 8.3 per cent.  
 On 0.263-in. opening—24.5 per cent.  
 On 0.093-in. opening—71.9 per cent.  
 Through 0.093-in. opening—28.1 per cent.

The amount of water kept in circulation, per ton of coal washed, is approximately 950 gal.; the quantity of makeup water added, per ton of coal washed, is approximately 41 gal.

#### TWO-COMPARTMENT CAST IRON JIGS EMPLOYED

The Risco plant of the Republic Iron & Steel Co., handles Mary Lee seam coal from the Risco mine. The plant consists of three two-compartment jigs of a modi-

fied Elmore type, having revolving valves but specially designed plungers. These jigs are built of cast iron and steel castings throughout and each has a normal raw coal capacity of 70 tons per hour.

This plant has more elaborate equipment for the preparation of the coal before it reaches the jigs than any plant in the district. Two rotary dumps are employed. One is used only when it is desired to inspect the contents of a mine car, to see if the miners are loading dirty coal. Ordinarily the entire output goes through the other dump. From here the coal is fed to a Marcus screen by a reciprocating feeder. The fines from this screen, passing through 1-in. perforations, are carried directly to the main belt conveyor; the balance of the product goes through a large single-roll crusher, then through a double-roll crusher and onto a shaking screen having 1-in. perforations. All coal passing the 1-in. perforations is conveyed by a belt to a set of short-stroke quick-acting screens having 3/8-in. perforations. Material passing through this screen can be made to bypass the jigs but the balance of the material is delivered to them.

OUTPUT CAN BE LOADED WITHOUT WASHING

Provision has been made for loading the entire output without washing. In that event, by manipulating the valves on the Marcus screen, any of the following grades can be produced: Lump, nut, lump and nut mixed, or run-of-mine.

The circulating water overflowing the settling tank, carrying in suspension a large quantity of fine coal, is pumped to a 70-ft. Dorr thickener, set at an elevation above the jigs. Two of these thickeners have been installed, the second one to be used as output increases. The clarified water from the Dorr machines returns to the jigs by gravity. This feed water to the jigs may be fed to the machines either above or below the plungers or to both places, as expediency may require. Fine coal from the Dorr machine consisting of 50 per cent solids and 50 per cent water, is sluiced to the main washed-coal conveyor and thence delivered to the washed-coal railroad bin. In transit it falls on the coarse washed coal, the water filtering to the bottom of the dragline conveyor, in the trough of which are three sections of thin copper plate perforated with fine slots which allow all water, free of coal, to return to the settling tank.

Cast-Iron Jig with Rotary Valve Mechanism

This is a view on the floor below that shown in the preceding illustration. There has been much controversy as to the relative merits of wood, concrete, cast iron and structural steel a materials of jig construction. It would appear that each has its place where it will serve to best advantage.

The operating officials of the Republic Iron & Steel Co. have furnished the following information:

Inasmuch as the output of the Risco mine has not been up to full capacity of the present jig equipment, rewash tables have not been installed and no thorough test of washer efficiency has been made. However, the following tests of operation show approximate results obtained at reduced capacity. Adopting 1.35 as the specific gravity of pure coal, the percentage of coal and impurities in the product going to the washer are as follows:

Flotation Test of Crushed Run-of-Mine Coal with Analysis

	Class Specific Gravity	Amount, Per Cent.	Ash Content, Per Cent.
Pure coal.....	1.35	78.7	7.28
Impure coal.....	1.35 to 1.40	4.7	14.19
Impure coal.....	1.40 to 1.45	4.3	18.24
Impure coal.....	1.45 to 1.50	2.4	22.13
Impure coal.....	1.50 to 1.55	1.2	28.51
Impure coal.....	1.55 to 1.75	1.5	35.85
Impure coal.....	1.75 and over	7.2	72.14

The average analysis of run-of-mine coal is: Volatile matter, 27.75 per cent; fixed carbon, 55.50 per cent; ash, 16.75 per cent; sulphur, 0.90 per cent.

Average quantities, by sizing test, are shown herewith.

Sizes and Percentages of Each of Varying Specific Gravities

Size	Per Cent	1.35 Specific Gravity	1.35 to 1.45 Specific Gravity	1.45 to 1.55 Specific Gravity	1.55 to 1.75 Specific Gravity	Per Cent sink at 1.75 Specific Gravity
1 in. to 3/4 in.....	18.8	60.7	12.6	3.9	3.3	18.9
3/4 in. to 3/8 in.....	45.1	79.0	9.9	3.9	2.6	4.6
3/8 in. to 20 mesh.....	27.0	89.5	3.5	1.9	1.6	3.5
Through 20 mesh.....	9.1	89.6	.....	.....	10.4	.....
Whole sample.....	100.0	79.7	17.8	3.0	3.2	6.3

The average analysis of the washed product is: Volatile matter 28.50 per cent, fixed carbon 62.25 per cent, ash 9.25 per cent, sulphur 0.80 per cent.

Loss of coal of 1.40 specific gravity in refuse, averages about 1.4 per cent. This can be materially reduced by rewashing the crushed bone on tables, as contemplated in the original plans of the plant. Total washer loss is 8.5 per cent to 9.5 per cent refuse.

Since this plant has been in operation, the mine has been producing coal largely from narrow work. Machine cutting on the narrow work on the bottom increases the amount of impurities in the fines, therefore, there has been no opportunity to bypass the 3/8-in. coal without washing and it is not possible to say if this plan will be feasible when a larger amount of coal is received from the mine. However, in the design of the plant it was arranged that should the 3/8-in. coal be too high in ash, this product, together with the recrushed bone from the second-compartment of the jigs, will be washed over tables. This should insure almost a 100 per cent recovery of coal in this washery.

By using Dorr thickeners, all fines from 60 to 200 mesh are removed automatically from the circulating water. Tests made in another plant show that return water from these machines carried only 0.15 per cent solids. Water going to these thickeners contains 6 to 8 per cent solids. The ash in the final product, using the tables to be installed, should be reduced to 8 or 8.25 per cent, as against a theoretical 7.28 per cent ash at 1.35 sp. gr.

Water circulated per jig is approximately 1,300 gal. per minute, the capacity per jig is 70 tons per hour. Make up water is equivalent to the amount of moisture loaded in the coal, that is, about 10 per cent when the draining conveyor is not operating. This is equivalent to approximately 25 gal. per ton of coal washed. When the draining conveyor is operating, there is practically no water lost at the plant as coal is loaded out containing only approximately 8 per cent moisture.

BREAKERS MAKE INCREASED OUTPUT POSSIBLE

The Flat Top mine of the Sloss-Sheffield Steel & Iron Co. produces Mary Lee seam coal and the entire output is crushed and washed. The plant contained, originally, crushing rolls and six two-compartment double-plunger jigs made by the American Coal Washer Co. These are modified Faust type machines having the driving mechanism located below them.

For several years, prior to 1921, the average yearly

Washery at Bayview Mine, Tennessee Coal, Iron & Railroad Co.

At the left appears the mine headframe, at the right the washery and near the center the conical sludge separation tank. This means of clarifying the circulating water is extremely simple and effective. The clarified water leaves the cone at the top and the sludge is drawn off at the bottom.

run-of-mine output was 408,716 tons. The washed-coal produced averaged 9.88 per cent in ash and the refuse from the washer contained 8 per cent of good coal. In 1921, it became necessary to increase the capacity of the mine; but neither the crushing plant nor the jigs could handle an increased output satisfactorily.

A Bradford breaker was installed and the two-compartment jigs were converted into single-compartment machines of double length. For 1922 and 1923, the average output of the mine was increased to 604,346 tons. The ash content of the washed coal averaged 9.11 per cent, and the loss of coal in the washer refuse ran 9.1 per cent. Unfortunately, the changes were made simultaneously and it is not possible to determine just how much of this increased capacity resulted from the installation of the Bradford breaker and how much from the change in the jigs. The company's engineers are satisfied, however, that the change in design of the jigs has increased their capacity.

Of the six jigs as originally installed, five were used for primary washing and the sixth to rewash the slate and hutch from the last compartments of the five primary machines. Under the new arrangement all six jigs are used as primary washers and no rewashing is necessary.

#### CONICAL TANKS RECOVER SLUDGE EFFECTIVELY

The Tennessee Coal, Iron & Railroad Co.'s washer, at Bayview mine handles only Pratt seam coal from the Bayview operation. The plant contains three, three-compartment Elmore jigs. The run-of-mine coal is first taken to a Bradford breaker. The portion passing through the breaker screen is reduced to  $\frac{3}{4}$  in. and smaller. It is then delivered to the jigs. In normal operation all the sludge is carried to the top of a conical tank.

If any delays occur, such as might arise from the breaking of an elevator or a main supply water line, all the circulating water from the washing plant is immediately drained to a ground sump in front of the cone sludge tank. When the plant is ready to resume operations, this water is elevated into the sludge tank and work started. This sump is necessary because all the drainage from this washing plant finds its way to the main water supply of the company's furnace and steel plant at Ensley, so every precaution has been taken

to prevent impurities reaching this supply. In a four-day test, it was found that the fine coal carried off by waste water from this washer amounted to only 8.7 lb. per 1,000 tons of washed coal produced.

Provision has been made for loading lump but under normal conditions all of the coal is treated in the washer. Considering the tonnage produced and the quality of the product one cannot fail to be impressed by the small size of this washing plant. This is partly because rewash jigs and tables are not used. The product coming from the last refuse valve on each jig is high in ash but as it makes a satisfactory boiler coal the company has found it cheaper to use it for steam raising (it is equivalent to only 6.53 per cent of the total raw coal) than to install the necessary rewash jigs or tables.

For the year 1923 the results shown in Table II were obtained at this plant; the data were furnished by the engineering department of the owning company.

Table II—Results Obtained at the Tennessee Company's Washery at Bayview Mine

	Per Cent	Tons	Tons
Raw coal delivered to washer.....			494,733
Washed coal to coking ovens, 1.37 sp.gr.....	82.05	405,931	
Boiler coal to steam plants, 1.37 to 1.56 sp.gr.....	6.53	32,295	
Refuse over 1.56 sp.gr., 11.42 to 5.4 percent float..	10.81	53,489	
Washer loss float at 1.36 sp.gr. in refuse.....	10.61	3,018	
	100.00		494,733

Number of 9-hr. shifts worked.....	56
Tons of raw coal per shift.....	87

Coal	Proximate Analysis Volatile Content, Per Cent	Fixed Carbon, Per Cent	Ash, Per Cent	Sulphur, Per Cent
Raw coal.....	26.42	61.14	12.44	1.76
Washed coal.....	28.18	67.06	4.76	1.30
Boiler coal.....	25.45	59.73	14.82	2.25
Refuse float (5.4 per cent).....			5.19	1.49
Sink (94.6 per cent).....			62.81	4.74

Sizing Tests			
Raw coal.....	Over $\frac{3}{4}$ in.	9 per cent	Note that per cent of sizes is highly variable.
Washed coal.....	Over $\frac{3}{4}$ in.	19 per cent	
Boiler coal.....	Over $\frac{3}{4}$ in.	20 per cent	
Refuse float (5.4 per cent).....	Over $\frac{3}{4}$ in.	14 per cent	
Sink (94.6 per cent).....	Under $\frac{3}{4}$ in.	42 per cent; ash 7.3 per cent.	
Inherent ash in coal at 1.37 sp.gr.....			4.2 per cent
Inherent moisture in coal.....			3.2 per cent
Washer efficiency: separation.....			88.23 per cent
recovery.....			99.39 per cent
Total efficiency.....			87.69 per cent

Water in circulation at this plant amounts to 600 gal. per ton of coal washed per shift or approximately 970 gal. per minute. Water lost amounts to 27 gal. per ton of coal washed. The average amount of power used equals 1.24 kw.-hr. per ton of washed coal produced.

## Modern Methods Are Used in Making Rock Dust on a Large Scale at Old Ben No. 9 Mine

**Rock-Dusting Plant Where Hard Rock Goes in One End and Fine Pulverized Dust Comes Out the Other**

A. Electrically-operated plant where the stone is pulverized and delivered to the mine car tracks. B. The rock is gathered into ordinary mine cars which are assembled at the foot of a plane leading to the top of the pulverizing plant. C. A car on the tipple discharging its load of rock. D. Pulverizer unit from which the rock is conveyed to the screens. E. In spite of the large quantities of dust in the air this motor gives little or no trouble. Incidentally the rock dust would prevent the spread of a fire in the wood-stucco building. F. Here's where the dust is delivered and may be packed in bags so that it may be transported about this mine or among the various other mines.

WHEN the officials of the Old Ben Coal Corp. operating in southern Illinois decided they were going to use rock dust to keep the mines safe they built a modern plant capable of turning it out in large quantities. Every modern means of conveying the material to and from the plant has been employed. Loaded cars into which the selected rock has been loaded are raised to the top of the building by means of a small cable hoist. When the car reaches its destination its contents is dumped into a bin and conveyed to the pulverizer. Motor-driven equipment reduces the rock and blows it through the sizing screens. On the outside of the

building the rock dust drops through a canvas pipe into sacks and cars.

Unlike the methods employed at many other mines, the Old Ben Coal Corp. has a systematic way of handling its whole plant. When our British visitors last spring wanted to see how rock dust was made and used in this country they were taken to this mine and there they were shown the complete process. Those who witnessed the demonstrations—proving the efficacy of rock dust staged by the officials of this company—have something worth while to remember about ways to make the mines safer.

# Alabama Has Made Great Progress in Coking Coal

Advanced Rapidly from Pre-War Smelting with Charcoal to Today's Oven Capacity of 7,836,000 Tons of Raw Coal—Leads the Country in Substituting Byproduct Units for Beehives\*

BY F. W. MILLER

Manager, Byproduct Dept., Sloss-Sheffield Steel & Iron Co., Birmingham, Ala.

**P**RIOR to the Civil War, there were several small charcoal furnaces for smelting the brown limonite ore that is found, in comparatively small bodies, throughout the central and north-central portions of Alabama. During the Civil War, these furnaces furnished charcoal iron to the Confederate government. No attention was paid to the large bodies of lime-bearing hematite ore that now supply the bulk of the ore used in the various blast-furnace plants of the Alabama district until the latter part of the 19th century.

When it was found that these ores could be worked satisfactorily in the blast furnaces, there was a comparatively rapid growth in the blast-furnace industry in the Birmingham district. As these ores are far more refractory than the limonite ores, this blast-furnace development was accompanied by the construction of beehive ovens to carbonize the coal, in order to supply the necessary fuel. The state's production of beehive coke in 1880 was 60,781 tons; ten years later this had increased to 1,072,942 tons; and in 1897 the production had reached 1,443,017 tons.

In 1898, the first byproduct plant built in the state was put in operation. This plant consisted of 120 horizontal-flue Semet-Solvay ovens, three flues in height by thirty flues in length with an average width of 16 in. The plant was constructed by the Semet-Solvay Co. for the Tennessee Coal, Iron & R.R. Co. and was located adjacent to the blast-furnace plant of that company

at Ensley. Coal was delivered from the Pratt mines by gravity tracks directly into bins of the ovens after having been properly crushed and washed at the mines. The coke was delivered by the Semet-Solvay Co. into coke bins of the blast furnaces directly from the quenching cars.

The coke production in 1898, for the entire state, was 1,663,000 tons; and in 1900, 2,110,837 tons. In 1902, four additional batteries of Semet-Solvay ovens were added to this plant. These later ovens were of the same dimensions but were four flues in height; that is, the heating wall was 80 in. high instead of 60 in., and the total coke production for the state increased to 2,552,246 tons.

In 1906, the Semet-Solvay Co. constructed, for the Central Iron & Fuel Co., at Holt, forty Semet-Solvay ovens of the cold-air type. These ovens are 100 in. to the coal line, 16 in. average width, and 30 ft. in length. No more byproduct ovens were added until 1911-1912, when the plants of the Woodward Iron Co. and the Tennessee Coal, Iron & R.R. Co. were constructed. The Woodward plant consisted of 170 Koppers ovens and 60 Wilputte ovens.

In 1911, the Tennessee Coal, Iron & R.R. Co. constructed four batteries of Koppers ovens 19½ in. wide, 8 ft. 6 in. to the coal line and 37 ft. 3 in. long. The plant at that time had an annual capacity of 2,146,000 tons of coal. In 1920, this company added two batteries of 77 ovens each, bringing the total number of ovens in this plant up to 434 and increasing its annual coal capacity to 3,340,000 tons.

This plant now supplies all the coke required by

\*Article entitled "Byproduct Coking in Alabama" to be read before the American Institute of Mining & Metallurgical Engineers, Birmingham, Ala., Oct. 13, 1924.

Two Batteries of Semet-Solvay Byproduct Ovens at the Plant of the Sloss-Sheffield Steel & Iron Co., Birmingham, Ala. Tar Tanks, Cooler Coils, Coal Bin, Pump House, Primary Coal

eleven active blast-furnace stacks of the Tennessee Coal, Iron & R.R. Co. and, in addition, is capable of handling some coke for the commercial market. In 1913, the coke production of the state had risen to 3,323,664 tons, 2,022,959 tons of which was byproduct coke and 1,300,705 tons was beehive.

In 1917, the Gulf States Steel Co., located at Alabama City, placed in run its byproduct plant of 37 standard Koppers ovens with an annual capacity of 250,000 tons of dry coal.

As a result of the stimulus of the World War, the Alabama Byproduct Corporation constructed at Tarrant, a suburb of Birmingham, fifty Koppers ovens having an average width of 16 in., height to coal line, 9 ft. 10 in. and a length of 37 ft. The Sloss-Sheffield Steel & Iron Co. began the construction of 120 Semet-Solvay ovens with an average width of 18½ in., height to coal line 11 ft. and a length of 36 ft. These ovens, which have the largest coking chambers of any ovens in the state, have a capacity of approximately 15 tons of coal per oven charged and an annual coal capacity of 970,000 dry tons. In 1923, the Alabama Byproduct Corporation added twenty-five ovens of the same capacity to their original battery, bringing the annual coal capacity to 456,000 dry tons.

The total coke production of the state for 1923 was 4,200,000 tons of which 268,000 tons was produced in beehive ovens and 3,932,000 tons in byproduct ovens. This means that less than 7 per cent of the total coal carbonized for metallurgical purposes in the state was carbonized in beehive ovens.

It is hardly necessary to go into the fundamental causes of this rapid displacement of the beehive by the byproduct oven. The byproduct oven represents a much larger capital outlay per ton of coal carbonized, but the byproducts are fully capable of carrying this increase. The more uniform grade of coke, the direct saving of coal through yield of coke, the conservation of coal resources and the reduction of labor cost, together with more favorable working conditions for labor are the major factors.

It is, however, noteworthy that Alabama, which has always enjoyed a plentiful supply of common labor

at comparatively low rates, has outstepped her sister states in her progress in coking. The annual capacity, in tons of dry coal, for this district is as in the accompanying table.

Byproduct Coking Plants in Alabama with Their Capacities	
	Tons, Dry Coal
Semet-Solvay Co., Ensley .....	730,000
Semet-Solvay Co., Holt .....	330,000
Woodward Iron Co., Woodward.....	1,760,000
Tennessee Coal, Iron & R.R. Co., Fairfield.....	3,340,000
Gulf States Steel Co., Alabama City.....	250,000
Alabama By-Product Co., Tarrant.....	456,000
Sloss-Sheffield Steel & Iron Co.....	970,000
	7,836,000

It will be noted that the combined coking capacity of all of these plants, if operated at their maximum production rate, will be equivalent to the consumption of 7,836,000 tons. Assuming an average yield of 75 per cent of furnace fuel, these plants will produce annually 5,362,000 tons of coke. As the maximum quantity of coke so far produced in the state in any one year (1917) was 4,892,589 tons, even when allowance is made for improvements in furnace capacity, which have been steadily taking place, the byproduct ovens are capable of producing all the coke required by the state without any assistance from the beehive ovens whatsoever.

There is no district in the United States in which the substitution of the beehive oven has been so complete as in the State of Alabama. The districts of Chicago, Detroit, Buffalo, and a few other points, of course, have no beehive ovens. The development of these points represent a transference of the coking operation from the mine mouth in Pennsylvania, Kentucky, and West Virginia to the point of demand. This transfer has been justified by the production of coke-oven gas for domestic and industrial uses and by making available valuable byproducts nearer the point of consumption.

As the South is proportionately the largest consumer of ammonium sulphate, practically all the ammonium produced by the Alabama byproduct ovens is produced in the form of ammonium sulphate and marketed to the various manufacturers of commercial fertilizer.

Sloss-Sheffield Steel & Iron Co. at North Birmingham, Ala. This View Shows Also Benzol Scrubbers, Fuel-Gas Equalizer and Exhauster Building

As the Birmingham district is the largest producer of cast-iron pipe in the world, it is also the largest consumer of coal tar for the dipping of pipe manufactured in this district.

The development of blended motor fuel has probably been carried further in the Birmingham district than anywhere else in the United States, and consequently almost the entire production of benzol is consumed within a short radius of Birmingham, by the automotive industry. During the late World War, practically all of this benzol was converted into pure products and consumed by the manufacturers of munitions.

The coke-oven gas from the various plants is largely consumed by industries and municipalities. The plant of the Sloss-Sheffield Steel & Iron Co. supplies domestic gas of approximately 550 B.t.u. to Birmingham through the Birmingham Electric Co. The Holt plant supplies gas to Tuscaloosa and to the ore-nodulizing plant of the Central Iron & Coal Co. The Tennessee Coal, Iron & R.R. Co. consumes its gas in its steel plant. In addition, it receives about 6,000,000 to 7,000,000 cu.ft. daily from the Semet-Solvay Co. at Ensley. The Alabama By-Product Co. has a 3,000,000-cu.ft. holder, in which it stores the surplus gas produced at night, thus making all its surplus gas available during the day. This has enabled the company, through a subsidiary pipe-line company, to supply gas to several large consumers.

The Gulf States Steel Co. consumes its surplus gas within its own steel plant, and the Woodward Iron Co. uses its gas under boilers, supplementing its blast-furnace gas to produce steam not only for its furnace plant but to supply power for its mines and other activities.

The boiler and power plant of the Sloss-Sheffield Steel & Iron Co., located at its byproduct plant, has a battery of eight Stirling boilers equipped to burn coke-oven gas, coke breeze in Coxe stokers, and pulverized coal. This power plant supplies the company's coal and ore mines, its quarry, two of its furnaces, in addition to its byproduct plant requirements. It also sells power. Extreme flexibility is required in order to be able to supply gas to the city in quantities varying over wide limits with the seasons and to take care of the rapid hourly fluctuations of its mine load.

Inasmuch as the conversion from beehive carbonization to byproduct coking has been so complete, the construction of byproduct ovens will be relatively slower, as it will be forced to follow the development of the blast furnace and steel industry. However, as the South is now consuming the greater part of the iron produced in this district and this southern demand is growing rapidly, additional blast furnaces, and probably steel plants, will be constructed and the building of byproduct ovens will keep pace with this development.

THE ROYAL COMMISSION ON MINING SUBSIDENCE, states *The Iron and Coal Trades Review*, proposes to visit Scotland on Oct. 16 and 17 for the purpose of obtaining by personal inspection of typical cases direct evidence of damage caused by subsidence.

The Commission is in consultation with the various Scottish Local Authority Associations with a view to selecting a number of representative cases. Damage to private property will be inspected, as well as local authority and similar undertakings. It is probable that the Commission will visit the Lanarkshire coal field Oct. 16 and the East of Scotland on Oct. 17.

It is not proposed to hear any oral evidence during the visit to Scotland, since the view of the Commission

is that evidence of this type can be heard more satisfactorily and with greater economy of time in London. Only a limited number of places can be personally inspected. In regard to evidence generally, the Commission is always glad to receive and consider photographs and statistics. In this connection the Commission desires it to be understood that what it wishes to obtain are brief descriptions of a few typical cases of severe damage, general statistics of costs incurred over a period of years, particulars of mineral reservation clauses in typical leases, reasoned and detailed proposals for the solution of the problem as a whole and similar evidence of a general and concise nature.

**There's No Squalor in This Coal Camp**

The town of Mohrland, Utah, at one of the United States Fuel Co.'s mines, is nestled in a place in the Wasatch range which gives it natural attractions and a wonderful outlook which are poorly shown by this photograph. There is plenty of room and fertile soil for grass plots and gardens and the houses are comfortable and kept in good repair. The company's community amusement hall is shown at the left.

# Alabama Coal Mining Methods Vary Widely

Seams 24 in. to 13 ft. Thick Lying in All Positions from Flat to 90 Deg. Pitch Test Engineers' Ingenuity—Panel and Longwall Systems Common—Drag Loaders Are Saving 25 to 50 Cents a Ton

BY MILTON H. FIES

Vice-President, De Barbelben Coal Corporation,  
Birmingham, Ala.

ALABAMA coal is won from thirty workable coal beds that range in thickness from 2 ft. to 13 ft., with an average thickness of 4 ft. The principal producing beds in the Warrior field are flat, or nearly so, whereas those of the Cahaba field range from slightly tilted to comparatively heavily pitching beds. It is to be expected that, on seams from 2 to 13 ft. thick, pitching from 0 to 90 deg., nearly all mining methods are used; hence a description of such methods must be more or less general.

Mines in Alabama are opened, generally, through drifts and slopes, although there are some vertical shafts in the state. The principal method of mining is the ordinary room-and-pillar. A modified longwall system is being used in several mines in the Cahaba field on pitches, and modified longwalls, or panels, are being used in several mines of the Warrior field.

To mine seams under 36 in. successfully the conditions must be favorable. Most of the thin seams mined lie flat. It has been found unprofitable, with very few exceptions, to mine thin seams that pitch. In most instances, thin seams are mined through drifts opened on the coal, although in a few cases such seams are reached by means of short slopes or shallow shafts.

Where this type seam is mined through drifts, the coal outcrops in hollows, and tram roads are graded along these hollows. Drifts or entries are turned into the hills, usually at room distances apart, either with double entries or an air course with each entry. Where the dip does not prevent, rooms are turned from both entries in a double-entry system or from the entry and the air course.

The depth of the rooms in thin flat coal varies from 125 ft. in 26 or 28-in. seams to 175 ft. in 36-in. seams. The thickness of pillars varies from 10 ft., where rooms are 20 or 30 ft. wide, to 40 ft. with 40-ft. rooms. The thickness of cover runs from 40 ft. to 300 or 400 ft.

A panel system in use in a drift mine in thin coal is shown in Fig. 7. The main entry, *A*, is opened from the surface and the main face entries, *B* and *C*, are parallel to and 1,600 ft. from it. Main butt headings, from which no rooms are turned, connect *A*, *B* and *C*. Double entries *D* and *E*, five to a panel, are turned from the main and main face entries. Each panel is surrounded by a barrier pillar that is ample to protect it. The headings *D* and *E* in each panel are developed by double gob entries, as shown in Fig. 8.

Rooms are turned on 80-ft. centers, each room having a double neck and with a double track. After the room is driven in from 50 to 65 ft., it is widened to connect with an adjoining room, until five rooms are connected. This affords a 400-ft. face, which in some instances has

been carried forward for 70 ft., although this face usually advances in steps.

To afford the miner an opportunity to load, switches are laid from the room track or, in some instances where the top permits, the track is curved around the face. A solid pillar 40 by 145 ft. is left after five rooms are turned. When expedient, pillars such as this are left, so that on one entry the pillar comes beyond room No. 5 and in the next entry beyond room No. 7.

The purpose of this panel system, in thin coal lying flat, is to afford means for robbing each entry as it is worked to its limits by leaving pillars of sufficient size to obtain a maximum recovery. The recovery of pillars in thin coal is difficult at best, and it has been found satisfactory to leave short thick stumps rather than long thin pillars, as was the practice in Alabama until recently. Of course, this method can be applied only where the ownership is in fee. Where the ownership does not include the surface, rooms 30 to 40 ft. wide, depending on the top, are turned with pillars from 10 to 20 ft. in width, depending on the depth of the overlying strata.

In the gob entries, which are driven usually to a height of 5 ft. 2 in. above the rail, 36 to 44 in. of rock above the coal is shot down and gobbed. The entries

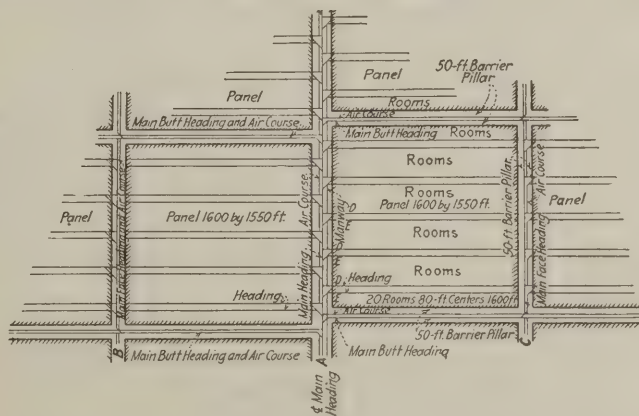

Fig. 7—Drift Mine Panel System

This layout is used in thin coal. The main entry is opened from the surface and the main face entries are parallel to and 1,600 ft. from it. Butt headings connect the face entries.

driven in the coal are of sufficient width to provide room for this rock. In coal 30 in. thick with entries clearing 5 ft. 2 in. above the rail, the entries must be driven 28 ft. wide in the coal to take care of the rock in an entry of standard width; i.e., 9 ft. wide at the bottom and 7½ ft. wide at the top. The cost of such yardage varies from \$2.56 to \$4.50 per running yard, depending on the thickness and hardness of the rock; the cost of yardage per ton varies from 25 to 40 cents.

When the hardness of the rock necessitates, drills with portable air compressors are used for drilling rock holes. Where such drills are used, it is common for

NOTE—The second part of a paper entitled "Alabama Coal Mining Practices" to be read at the Birmingham meeting of the American Institute of Mining and Metallurgical Engineers, Oct. 13.

the miner to drive his entry into the coal, say from 60 to 100 ft. ahead of his brushing. He then comes back and sets his breaking timbers, after which the drill runner spends the entire shift in the entry drilling the rock. A disadvantage of this method is that the miner cannot load coal each day, and utilizes his spare time for handling his rock, but it enables the drill runner to accomplish better results for he does not have to transfer his drill and compressor during the shift.

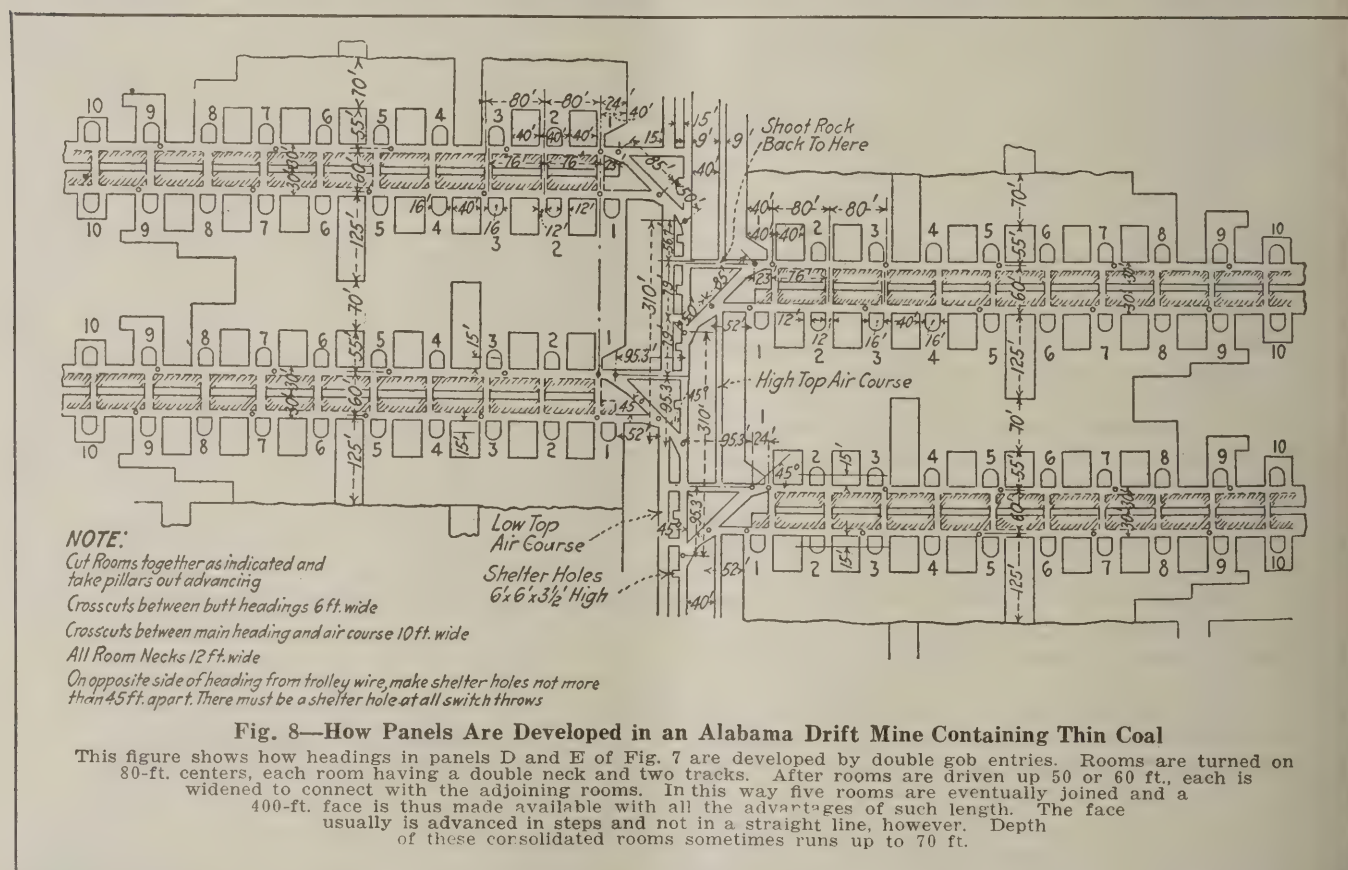

Coal lying as described is usually undercut with electric machines of the low-vein type. In some instances, one track of the room is brushed, that is, from 6 to 18 in. of rock is taken down over the roadway to admit the machine.

There are some modifications of the method described

occurred and the fall rode the face to a slight extent. The wall was then cleared and, instead of using timbers along the face, cribs were built every 10 ft. and left in place. The result was the overburden crushed the cribs located back from the face and no falls occurred at the face.

From an application of this system an apparent saving of 25 to 50 cents per ton has been effected, when the work progressed smoothly. In addition, the lump percentage was increased. The problem is one of control of roof subsidence, which must be worked out through experience, and the training of labor that has had no previous experience on walls.

Mining a flat seam of medium thickness is somewhat different. Much of the coal used in the manufacture

of mining thin coal lying flat. At one mine, in 30-in. coal, an experiment is being made with mechanical loading. While this method bids fair to prove successful, its consummation is not definitely assured.

Two cross entries, as indicated in Fig. 9, were turned 245 ft. apart in a drift mine. A pillar 75 ft. wide was left to protect the main entry and the cross entries were connected. In one cross entry, A, the bottom was taken up instead of brushing the top; in the other entry B, the top was brushed to entry height.

The face, or wall, 200 ft. in length is mined advancing. The coal is undercut with a chain machine, with 6-ft. cutter bar. Four rows of heavy timbers, set about 4 ft. apart were placed up to a point 5 ft. from the face, and, as the wall advances, the rear timbers are removed. A drag loader, 4 ft. wide, loads the coal directly into the cars placed in entry A, which is driven 250 ft. ahead of the wall.

Cribs placed "skin to skin" in two rows protect both entries. When the wall had advanced 100 ft., a break

of coke for the blast furnaces of the state is mined from such a seam—the Pratt. In the smaller mines, the prevailing method of mining is to drive a main opening through the center of the area to be worked. This opening is driven for single or double track, depending on the tonnage desired. It is necessary to blast down about 18 to 24 in. of roof to give height for a good haulageway. In some mines, a slab is driven with the haulageway wide enough to gob all the brushing rock; in other mines, the brushing rock is hauled to the surface, or gobbled in crosscuts, and rock eyes cut at intervals along the ribs.

An airway 12 ft. wide is driven on each side of the main haulageway, a pillar 30 ft. thick being maintained. Room entries are turned from the main haulageway measuring approximately 300 ft. center to center. After allowing 18 ft. for the width of the entry including the slab, 20 ft. for the airway pillar, and 12 ft. for the width of the airway—a total of 50 ft.—there remains 250 ft. for the length of the room. This is

Experience with mechanical loading, generally in Alabama, is more or less a matter of conjecture; its success has not been proved. On account of the partings in the

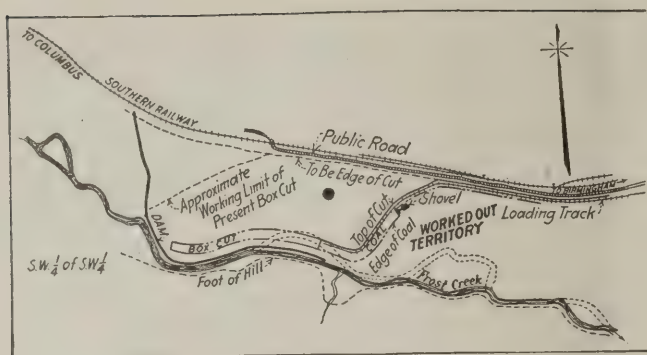

Fig 11—A Successful Strip Operation

Coal 42 in. thick but with a 4-in. parting is uncovered by a shovel equipped with a 2½-yd. bucket on a 60-ft. boom and loaded by a smaller shovel. A dam protects the workings against flooding. In most of Alabama's 10 strip pits the labor cost of coal loaded on railroad cars is from 50 to 70 per cent of the cost entailed in underground mining.

thicker seams, mechanical loaders of the Joy type have not been used.

Thick seams lying flat are mined in practically the same manner as thin seams and those of medium thickness. The rooms are deeper and the development neces-

heel, or knee, on the loose end and in the center of the undermined half of the face. These knees are cut out before the shots are fired. After the miner has undercut the coal as shown, he must stand up while he cuts out the heel, so that the hazard from falling coal is minimized. A safety travelway for the miner is provided in all rooms. As shown in Fig. 12, it parallels the room track.

#### POWER STRIPPING AND LOADING PRACTICED

There are eight or ten coal-stripping operations in Alabama, all are on seams that lie flat; coal from 28 in. to 6 or 7 ft. is being mined. From 4 to 40 ft. of cover is removed from coal with shovels of the larger type, the small or loading shovel follows the stripping shovel and loads the coal either into railroad or mine cars. Practically all the stripping coal is washed before it is shipped to the consumer.

A successful operation is shown in Fig. 11. At this operation levees are built and the creek changed when necessary to protect the open cut. The coal is 42 in. thick with a 4-in. parting.

At this mine, the total overburden is prepared for

FIG. 12  
Room in a Thick  
Flat Seam

One half of a room's width is driven ahead and the coal is shot down and loaded while the other half is being undercut by hand. The miner must leave a heel or knee on the loose end and in the center of the undermined half of the face. These are cut out before the shots are fired.

sary for a given tonnage is less; the production cost in some instances is only one-half the cost of producing coal in seams 30 in. and under. Under favorable conditions, seams 5 to 10 ft. thick, with partings from 24 to 30 in. are profitably mined. In some cases the miner actually removes and gobs ½ ton of rock for each ton of coal loaded. When mining is done with a chain machine, the bottom bench is shot and loaded, the "middleman" is forced down with a bar or wedge and gobbled and the top coal is then shot and loaded. A section of a seam with a 12½-in. "middleman" so mined is shown in Fig. 10. The washer loss at this mine is in excess of 20 per cent.

A room in a mine on one of the thick seams, lying comparatively flat, is shown in Fig. 12. This illustration shows that one-half of a room's width is driven ahead, the coal shot down and loaded while the other half of the room is being undercut by hand. This is a safe method, for the miner is required to leave a

the stripping shovel by drilling holes, on 18-ft. centers, to within 1 ft. of the coal and shooting them with two and one-half sticks of 40 per cent gelatin, using a 5-in. by 16-in. cartridge. The box cut is approximately 1,100 ft. long, and develops approximately 14 acres or 90,395 tons. The box cut corresponds to narrow workings in underground workings. After the box cut is driven, slabs are removed along the face until the workings advance to their limits, when another box cut is driven into the property.

There are some variations in this method. At some operations, the shovels work in a circle; in others, they work along the side of hills until the overburden becomes excessive. Where conditions are favorable to strip mining, it has been found that the cost of labor per ton for coal delivered on the railroad cars is from 50 to 70 per cent of the cost of underground mining for a seam of like thickness. This constitutes a decided advantage for this method of mining.

# National Safety Congress at Louisville Gives Proof Of Progress During Past Year

Membership Has Gained 14 per Cent—Mining Section Attended by Engineers from All Over Country—Electric Hazards and Organization for Safety Discussed—Adams Throws New Light on Accident Accounting

**A** GAIN of 468 members during the past year raising the membership from 3,321 to 3,789 is a reassuring symptom of the health and vitality of The National Safety Council, now in its thirteenth year. Another healthy sign is that its gross revenue was \$377,448.63 for the fiscal year ended July 31, the membership dues alone bringing in \$187,929.51. Nearly 500,000 copies of the Safety Calendar were distributed.

The attendance at the Louisville Congress was large; just *how* large it was difficult to determine because many who attended failed to register. It seemed, however, to measure up in every way with the best of previous conferences, the mining section having an attendance of 60 to 70 at each of its three meetings.

Stray electric currents and their dangers formed the subject of E. E. Jones' paper at the Mining Section meeting on Tuesday. That paper had reference to electric fuses but J. L. Boardman, safety engineer of the Anaconda Copper Mining Co. declared that two serious accidents had occurred at the Anaconda mine from the premature discharge of shots not thus provided.

George Martinson, safety engineer for Pickands, Mather & Co., Hibbing, Minn., said that at one of the open ore pits of that company forty holes with an aggregate charge of 800 lb. of dynamite had been exploded during a storm. The holes were awaiting the action of the electric battery but the storm delayed the proper firing of the charge which was exploded, however, by the electric discharge of the storm.

He wondered if the wires were twisted the potential in the wires would become uniform so that no current would pass through the detonators. He said it must be remembered that the leads were but indifferently coated with insulating material and were in contact with iron ore which forms a ready conductor for any stray current the earth might contain. Mr. Jones believed that twisting the terminals as described would render the charge safe. Mr. Martinson stated that now the shooting gang when it saw a storm approaching hurried up its shooting to prevent a premature explosion but conditions did not always make such prompt action desirable.

J. T. Ryan said that in a mine at a point about 250 ft. beyond the trolley line a difference of potential of 6 volts between water pipe and rail was observed. One could put off a detonator at any time by connecting it with these points.

"Safety Kinks" was the title of C. L. Colburn's address, his kinks referring solely to meeting the human or moral hazard. He described the steps to be taken to get the men organized for safety and to keep them thinking in that direction.

That we need statistics to sell safety was the conclusion of W. W. Adams. He said that only by a careful statistical record can a sound and reliable basis

be established for the information and guidance of those engaged in accident prevention work and added "Thus also will the work be removed from the realm of things subject to the vagaries of individual judgment and brought into the realm of things concrete and measurable, known alike to all who need the information and not subject to loss with the changing fortunes or the passing of any individual."

Mr. Adams called attention to the need for statistics that will show not only the number receiving injury by reason of any given hazard but also the number exposed to that hazard, thus making it possible to ascertain the accident-frequency and severity rate for each occupation. He gave the accident rates of various mineral industries as in Table I.

Table I—Accident-Frequency Rate for Several Industries

	Per Million Hours
Coal mines.....	96
Metal mines.....	91
Quarries producing crushed stone.....	70
Smelters (not including iron blast furnaces).....	64
Mills.....	62
Beehive coke ovens.....	49
Quarries producing dimension stone.....	47
Byproduct coke ovens.....	47

Quoting the *National Safety News* figures for other industries than mining Mr. Adams gave the severity rates as in Table II.

Mr. Adams' papers showed some extremely interesting tables. From them has been constructed Table III.

J. T. Ryan said that in British and other European mines the percentage of accidents due to roof and sides was even higher than in America and that the British government was offering a prize for the best suggestion for the reduction of accidents of this class.

At Wednesday's session Francis Feehan, mine safety commissioner, U. S. Bureau of Mines, addressed the mining section on "Organizing the Mining Industry for Safety." Though his paper has not yet had the approval of the U. S. Bureau of Mines, it may be permissible to refer to it briefly. Mr. Feehan compared the figures of fatalities per 1,000 full-year workers in the United States, Great Britain, France, Belgium and Prussia since 1911 and showed that with the exception of Prussia the death rate in America's coal mines was approximately 3½ times that in the coal-mining industries quoted.

Mr. Feehan remarked that this was a serious indictment and added, "We lead the world in mining engineering, but we have grossly neglected the most important factor in production which is the conservation of the lives and health of those employed in the

\* Mr. Adams makes this "Shafts and Cages" in his metal-mine casualty figures

mines." He called attention to the fact that rarely is a mine closed that is in a dangerous condition and said, "How seldom are the mine owner, his officials or the mine workers prosecuted for violating the mining laws?"

With equal energy Mr. Feehan assailed the mine owner and the mine worker, declaring that the latter constantly made the charge that the employer is not concerned about his safety but only about production. "Is not this," said Mr. Feehan, "true also of the mine worker?" Mr. Feehan said the miner frequently failed to make the inspections required by law and as a result was maimed or killed.

Reference was made also to the Gay Coal & Coke Co., Logan, W. Va., that for seventeen years had not had a single fatal accident and yet had put out 2,500,000 tons of coal. Hardly anything in other industries could compare with this record. The general run of industries can be adequately protected by engineering. Almost every condition can be foretold and provided for. But the mine roof is not designed by engineers. It is an uncertain factor of varying quality. In places it is hardly a hazard, in others it is a perpetual menace. We cannot take it down and examine it and then, put it up again if we approve it or send it back to the manufacturer if we don't like it. It is what it is, but in any event we don't know just exactly what it will do.

The railroads have reduced accidents but in their case the blue sky above them is not in constant danger of falling and consequently only in tunnels are there dangers similar to those encountered in the coal mines and where these tunnels can be lined even these dangers are lessened. Moreover transportation underground is made hazardous by the small size of the units making elaborate breaking and coupling devices difficult of installation and by narrow, low roadways.

The problems encountered in mining, said one

speaker, are less amenable to engineering treatment, and furthermore, the decrease in accidents in the last few years may be less in mining than in other industries partly because the mining industry had been planning accident prevention for years and had long been subject to legal supervision and so was already experiencing, before the general reform, the advantage of its own specific reformatations thus making the opportunities for reform in the mining industry less promising than in other industries.

Theodore Marvin in the absence of N. S. Greensfelder delivered the latter's paper on "Safety in the Use of Explosives." Mr. Marvin declared that it was safer for a miner to use explosives than it was for a pedestrian to travel the city streets. About one life was lost for each 4,279 men employed, whereas in 1923 the fatalities from automobiles in the biggest cities have run from one for every 6,571 to one for every 2,633 of population. In some cities there is more risk by far that the ordinary citizen will be fatally injured by an automobile than that the miner will be killed by his handling of explosives.

### THREE TROPHIES FOR ACCIDENT PREVENTION

Mr. Marvin announced that in conjunction with the U. S. Bureau of Mines *The Explosives Engineer* would award three trophies, one to that coal mine, one to that metal mine and one to that quarry open-pit mine which has in any year the least loss of time from all classes of accidents in proportion to total hours of work performed, the accidents ordinarily classified by the Bureau of Mines carrying a double penalty.

To promote safety in the use of electricity J. B. Johnson, mechanical engineer of the United Verde Copper Co., Clarksdale, Ariz., said that for transmission nothing in excess of 6,600 volts should be used underground. It is seldom necessary to use anything over that voltage and unless the underground transmission line is unusually long, say over two miles, the standard pressure of 2,200 volts is sufficient.

Most engineers would say that in coal mines high voltages such as these should not be transmitted underground, but conditions similar to those of metal mines are found where the rising hills and dipping seams make depths prohibitive for shafting or for the lowering of cables in a borehole and in that case an underground transmission line of two miles length at high tension might be desirable.

The main feeder lines carrying 2,200 volts should, Mr. Johnson said, be insulated with a lead-sheath covering and flexible armor should be used. Such a cable is proof against moisture and being flexible can be anchored direct to timber sets or walls of tunnels and drifts. The metal sheaths are proof against stray induction currents. Mr. Johnson declared that the use of standard cable with metal sheaths was not desirable as moisture condenses within the conduits and wherever such construction is used provision must be made to trap the moisture and drain it off at suitable intervals. Mr. Johnson discussed feeder lines in hoisting shafts, electrical hoisting and its safe control.

J. W. Reed declared that he regarded these voltages as excessive but Mr. Johnson declared he was referring only to transmission currents. This did not satisfy Mr. Reed who takes a view somewhat common among coal engineers that high-voltage cables are undesirable in a mine. Metal miners are not so opposed to high potential because it is almost essential under their

C. B. AUDEL

Newly elected President of the National Safety Council. He is safety engineer, Westinghouse Electric & Manufacturing Co.

conditions of operation. With them it is often a choice between high-tension transmission underground or no electrical current. Some coal engineers have gone to high tension even though conditions do not make it so absolutely imperative in coal mines.

In reference to transformer rooms Mr. Hall remarked that it might be well to recommend not only that they be "fireproof and have quick-closing air doors for isolation in case of accident" but that the floor be well sanded, that the doors be held in place by a cord that would burn readily and permit the doors to close in case of fire and that a sort of low dam or sill be built at the entrance that would prevent the issuance of oil should a transformer be destroyed and the oil be precipitated over the floor of the room.

#### CARE IN DETAILS IS NECESSARY TO SAFETY

J. F. MacWilliams' paper on electric starting appliances showed in detail how every fuse or starter should be made a matter for careful study so as to avoid those hazards which even safety devices themselves are prone to introduce. Mr. MacWilliams declared that in the coal-mining regions, the undermining and the fracturing of the ground made the coal measures unnaturally dry and so introduced an electrical hazard, for it was difficult to get a good ground in material so lacking in the power of conducting currents. Quite generally in moist soils one could get, in grounding, a resistance of a half an ohm, but where the soil had been dried by the mine excavations the resistance might rise to 80 ohms.

J. B. Johnson remarked that pipes in the mines furnished a poor ground for they might be dismantled and the ground destroyed. The pipes are not under the electrician's supervision and so may be removed at any time, either entirely or in part, leaving the machinery without a proper ground. Furthermore, in a pipe there might be a gasket that would insulate one part of the pipe from another and thus prevent the transference of the current from the bedplate of the machine to the water in the sump. J. L. Boardman said that accidents from lack of grounding might occur by reason of the anxiety of electricians to get home at night. Some men who were working on a motor at the Butte mines were delayed by the exigencies of the occasion till after whistle-blow. They left without replacing the ground wire. They argued that tomorrow morning would do for the completion of the work, as the motor would not be used during that night. However, it was used, and, not more than five minutes after the electricians left the motor thus unprotected, an accident happened. In another case lights were connected in series, and the wire from these lights passed to a compressed air line which later was broken. A man stepping on the pipe and reaching over to a car was shocked and killed.

The nominating committee recommended the following members of the mining section for election: R. Dawson Hall, engineering editor, *Coal Age*, New York City for chairman; J. L. Boardman, safety engineer, Anaconda Copper Mining Co., Butte, Mont.; J. W. Reed, safety engineer, Consolidation Coal Co., Fairmont, W. Va.; R. B. Ageton, Tristate Zinc & Lead Ore Producers' Association and A. A. Bowden, safety engineer, Pickands, Mather Co., Ironwood, Mich., as vice-presidents; T. T. Reed, director of Safety Service of the U. S. Bureau of Mines, was nominated secretary. The men whose names were presented were duly elected. It was decided to form two committees, one

on collegiate education in safety and the other on elementary education on the same subject. It was suggested that the Bureau of Mines might be induced to prepare and publish an elementary textbook on the subject of safety. J. L. Boardman said that at least 40 per cent of the questions in a foreman's examination should deal with safety exclusively.

In the round-table discussion that followed Francis

Feehan answered some exceptions taken to his paper and particularly to his statement that employment in mining can be made safer than in any of our large industries. It is encouraging to learn from this that coal mining is an inherently safe industry.

At the annual banquet Col. A. B. Barber, of the National Safety Conference, spoke on behalf of Secretary of Commerce, Herbert Hoover in relation to the big meeting in highway-traffic safety to be held in

L. A. DuBlois

Recently elected vice-president in charge of general activities of the National Safety Council. He is safety engineer, E. I. du Pont de Nemours & Co.

Washington in December. H. C. Spillman declared in his address that as man made machines, man power was superior to machine power and should be more carefully conserved. H. Walter Forster discussed the value of the safety engineer and suggested that his ends were best attained by encouraging the foreman to tell what he is doing for safety whether the work he has achieved has been unusual or merely ordinary, the safety engineer more or less casually and inoffensively slipping in an idea that might correct some ill-advised condition and practice. Strickland Gillilian, of Philadelphia, closed the post-prandial entertainment with a half-hour of merriment. The toastmaster was Dr. Charles E. Woodcock, Bishop of the Episcopal Diocese of Kentucky, well-known for his eloquence and wit.

#### NEW STAFF OF OFFICERS DULY ELECTED

Announcements were made of the new officers of the National Safety Council: President, C. B. Auel, safety engineer, Westinghouse Electric & Manufacturing Co.; vice president in charge of public relations, L. R. Palmer, Equitable Life Assurance Society, New York City; vice president in charge of general activities, L. A. DuBlois, safety engineer, E. I. Dupont de Nemours & Co.; vice president in charge of public safety, David Van Schaack, Aetna Life Insurance Co., Hartford, Conn.; vice president of local safety councils, George T. Fonda, Fonda-Tolsted, Inc., New York City; vice president in charge of industrial safety, Henry A. Reninger, Lehigh-Portland Cement Co., Allentown, Pa.; vice president and treasurer, C. B. Scott, Bureau of Safety, Chicago, Ill.; Secretary and managing director, William H. Cameron, Chicago, Ill.

## News Of the Industry

### Co-operative Marketing Seen as Step in Cutting Coal Cost

Advantages Shown in Distribution of Farm Products—Legislation to Be Sought to Extend Benefits to Other Industries—Fear Conflict with Anti-Trust Laws

BY PAUL WOOTON

Washington Correspondent of *Coal Age*

Co-operative marketing among farmers has been so successful that a determined effort will be made at the coming session of Congress to obtain legislation which will accelerate even more this striking development. In 1915 there were 5,400 farmers' co-operative associations with 650,000 members. In that year sales through these organizations aggregated \$635,000,000. During 1923 the sales through farmers' co-operative marketing associations increased to \$2,200,000,000. At the end of 1923 there were 10,160 organizations in the United States, with a total membership of 2,025,600.

The advantages of this form of marketing have been proved beyond all peradventure. The effort is to be made at the next session of Congress to remove some of the obstacles in existing law which are having a hampering effect, and to further encourage this trend. In all probability this legislation will be couched in such form as to extend its benefits to other industries. It will be recalled that Secretary Hoover nearly three years ago proposed co-operative marketing, within districts, for bituminous coal.

The advantages of co-operative marketing, along lines more nearly analogous to coal, are shown in the highly successful British Sulphate of Ammonia Federation. The workings of that organization were studied carefully by Americans who attended the World Power Conference at London.

#### Marketing Beset with Difficulties

Like most byproducts there are unusual difficulties in marketing sulphate of ammonia. Formerly the British coke makers, which in that kingdom means the coal companies, disposed of their sulphate of ammonia independently, at any price which might be available when their stocks reached a point at which they no longer could be carried. It was sold through brokers and exporters. It was found, however, that the exporters were putting their heads together and withholding purchases until they broke the market. These tactics drove the producers into an association in self-defense.

The organization thus formed sells

the entire output of its membership, which comprises 95 per cent of the output of the British Isles.

When a producer delivers his output to the federation he is paid 60 per cent of the price which the association expects to realize from its sale. The remainder is paid to him at the end of the month in which the sale is made. From the total realization is deducted the small expense of marketing and 1s. a ton for extension work. This takes care of advertising expense and of the demonstrators maintained in the field to show farmers how to use fertilizer in that form. Large numbers of these demonstrators now are being sent abroad to explain the use of sulphate of ammonia to farmers in other countries. In fact, more is being spent in this way than all other costs of selling combined.

#### Treat Small Producer Fairly

The federation is an absolutely democratic organization. Every producer has voting representation in proportion to his tonnage. There is representation on a geographical basis and on an industrial basis, since ammonia production is not confined to the manufacture of coke. The oil-shale industry and gas-producing plants are important contributors to the pool. The organization has been extended to the British colonies. Producers in India already belong and those in Canada and Australia are expected soon to join. The federation is so organized that there can be no discriminations against small producers in favor of heavier shippers.

A striking fact in connection with the working out of this plan is that it has proved to be equally advantageous to the consumer. Formerly there were as many different prices for sulphate of ammonia as there were railroad stations in the United Kingdom. The federation immediately established uniform prices. Its product is laid down at any railroad station in the British Isles at the same price. It has extended a great protection to the purchaser of small lots. Sales are made at a circular price announced in advance and guaranteed against change for a period of three months. The

farmer thus can tell what his season's sulphate will cost and he does not have to stop to figure freight rates or worry about changes in the price.

In the same way the federation announces its prices in advance for the export trade. In some countries, to develop its use, a price under the cost of production is made. Thus the costly business of education is carried by the entire industry—an important feature of the business which could not be undertaken by individual producers.

This sort of marketing may conflict with the anti-trust statutes in this country, although the opinion has been expressed that co-operative marketing of coal, so long as it is confined to a single district and so long as competition is maintained between districts, does not violate those laws. At any rate, it would be charged here that such an association would sell at low prices abroad and charge monopoly prices at home. The actual result in Great Britain is exactly the opposite. The average selling price in the British Isles during 1923 was substantially lower than the export price.

The whole scheme has demonstrated the value to all concerned of co-operative marketing. The volume of business handled compares quite favorably with that which would be involved in a similar marketing association among the coal producers of a single district.

There are other examples in Great Britain of successful co-operative marketing enterprises which should be considered by the coal trade in this country in connection with the legislation which will be discussed when Congress meets. The Yorkshire Gas Coal Association maintains standards of preparation which it guarantees. The members advertise jointly through the association.

#### Steam Coal Men Organized

Producers of steam coal in Yorkshire also have an organization known as the South Yorkshire Hard Steam Coal Association. Its production is almost entirely water borne, either in the export or coastwise trade. With the idea of maintaining standards of quality the association gives a certificate to the buyer to the effect that his shipment is the "best South Yorkshire hard steam coal." The organization has an arrangement with the railroads at ports to provide an independent inspection. The railroad examiner also issues a certificate as to quality and as to the mine from which the coal comes. He also certifies as to weight. By this means the producers protect themselves against the irresponsible company which would trade on the general reputation of the district.

## Anthracite Mines Flooded When 8.6 Inches of Rain Falls in Two-Day Storm

*Special to Coal Age*

Scranton, Pa., Oct. 6.—Anthracite mines in the section bounded by Carbondale on the north and Hazleton on the south suffered heavily from the flood which followed the heavy rains throughout the anthracite region last week. The Hudson Coal Co. was the heaviest loser though several other companies also were hard hit. In Wilkes-Barre a flooded creek changed its course and emptied into the mines through a cave-hole in Hollenback Park. Mine cars, bales of hay, timber and steel rails were used in a fruitless effort to form a network over the cave and stop the water from entering the workings. In the meantime all mine workers were ordered from the operation. The situation was similar to the one confronted by the Glen Alden Coal Co. last spring, when the Lackawanna River flooded through a manway and filled several veins, crippling five mines and disabling the million-dollar pump-room located in the Sloan workings, as well as taking a toll of two lives.

After unavailing efforts to check the flow of the water, dikes were constructed and the course of the stream was finally diverted from the workings. The operation will be idle for several weeks until the workings are cleared of water. The underground pumps were submerged and ceased functioning soon after the deluge.

At Larksville the Loree No. 5 colliery of the Hudson company suspended operations on noon of the first day of the rainstorm, when it was found the pumps were not capable of handling the rush of water into the workings.

In the Hazleton region nineteen mines were idle on Monday and eighteen on Tuesday due to excessive water. The loading of cars at the collieries in the lower region was reduced from the normal output of 650 to 136 on Monday and 130 on Tuesday. It was not until the end of the week that the operations began to produce normally.

Water pouring into the mine workings through numerous cave holes caused the Red Ash vein of the Pennsylvania company's No. 7 colliery to become flooded on Tuesday night and threw 350 mine workers idle for three days.

A report from the Lehigh field stated that 8.6 in. of rain fell during the two days' storm. The eighth level of the No. 1 slope in the Hazleton colliery of the Lehigh Valley Coal Co. was flooded, the Crystal Ridge Creek having broken into the mine. The Hazleton Shaft and the Stockton openings likewise were flooded. Production was held up several days.

A substantial cement bridge just finished at the Crystal Ridge road of the Cranberry Creek Coal Co. over a small creek was dynamited by the coal company because it held back flood waters during the storm and caused them to pour into mine openings. The creek became a torrent at the height of the flood. Several sections of the mines were flooded.

## Docks Are Ruthless, Says Federal Trade Commission

The report of the examiner for the Federal Trade Commission, in the charge against the Northwest Coal Dock Operators' Association, is to sustain some of the accusations of unfair methods against that body. He finds it to be guilty of unfair competition against the all-rail trade and that it aimed to drive the latter out of its field, but finds also that price cutting has gone on within its own body and that it has been so ruthless that one dock concern lost \$1,000,000 in a price war.

## Hoover Silent on Status Of Trade Associations

Efforts recently begun by the Chamber of Commerce of the United States to obtain an expression from the Commerce Department as to the legal status of trade associations have proved unavailing thus far, it was admitted by Secretary Hoover last week. He said that he had informed the special committee of the chamber that the interpretation of the Sherman Anti-Trust Act was not a matter for his department and referred it to the Attorney General. Mr. Stone has already indicated an unwillingness to outline a government policy toward trade associations.

Mr. Hoover, however, indicated the belief that there would be some governmental agency, such as the Federal Trade Commission, which would be in a position to help business interests through the clarification of the law. He felt that the establishment of such machinery would be very helpful and quite distinct from any idea of attempting to advise business as to the law and anticipating court decisions.

He described as "a fatal mistake" the failure of Congress to include the suggested functions in the scope of the Federal Trade Commission when that agency was created.

## R. H. Lansburgh Named for Dr. Meeker's Place

Governor Pinchot has appointed Richard H. Lansburgh, of Swarthmore, professor of industry at the University of Pennsylvania, as state Secretary of Labor and Industry, succeeding Dr. Royal Meeker, who has presented his resignation, to take effect Oct. 15. Mr. Lansburgh has for several years been classifying the employment of state workers at the Capitol at Harrisburg and in state institutions. The Governor in announcing the appointment said he is of the opinion that Mr. Lansburgh is the best equipped man in Pennsylvania for the place.

The new head of the department will enter his work with a thorough knowledge of its functions, for he classified and fixed the salaries of its 600 employees. He has few illusions regarding the position.

## West Virginia Miners Quit When Wages Are Cut

Two hundred and seventy miners employed at the Glendale mine of the Glendale Gas Coal Co., at Glendale, W. Va., refused to go to work Oct. 1 after they read a bulletin announcing a contemplated reduction in wages to the scale of 1917. Not an employee entered the mine and the suspension will be indefinite, so far as the officials of the mine can say.

Sheriff John Hazlett, of Marshall County, was warned of the strike and asked to be ready in case trouble starts. It was reported, however, that the strike began in an orderly manner and there was little indication that friction would develop.

The Glendale mine has not been unionized.

Many union miners employed by the Bethlehem Mines Corporation, a subsidiary of the Bethlehem Steel Corporation, at its Barrackville mine, in Marion County, West Virginia, also refused to work when notices were posted stating that on and after Oct. 1 the mine would be operated on an open-shop basis with the 1917 wage scale in effect. Hearing a rumor that a shift would go to work at midnight on Oct. 1, union mine workers patrolled the roads leading to the mine in order to dissuade anyone from going to work. No disturbances were reported, however. The Dakota and Barrackville plants are the only mines of the Bethlehem Mines Corporation in West Virginia which within the last two years have been operated in agreement with the union.

## Jackson Resigns Presidency Of District 23

Lonnie Jackson, for four years president of the miners' union of District No. 23 (western Kentucky), resigned from that office Sept. 30, the resignation to become effective Oct. 1. Jackson gave no reason for his action, but indicated that he was considering entering the real estate business. He will continue to act as Mayor of Central City, he said.

Union miners in the district have been on strike since last April, when coal operators announced a wage cut, which miners declined to accept. Several mines have resumed operations in recent weeks, but they have furnished employment to only a minority of the union workers.

## To Resume in Pomeroy Field

After several conferences between operators and officials of the United Mine Workers in the Pomeroy district of Ohio an agreement has been reached whereby the union has made certain concessions as to dead work and day work which will help in reducing mining costs. The agreement is quite similar to that recently concluded between miners and operators in the Hocking Valley field at Logan. It is expected that as a result of the agreement mines which have been idle for some time will be placed in operation soon, as the demand for domestic sizes is improving.

## Equipment and Labor Useless Without Capable Management, Says Grant

A strong plea for the recognition of management as one of the constituent elements of modern business was the high light of an address by Richard F. Grant, president of the Chamber of Commerce of the United States, before the Philadelphia Chamber of Commerce, Sept. 24.

"In a very large measure," he said, "the great advancement of our country is due to those men who have had the vision and ability to organize and develop our vast resources and to convert them to the uses of our people. Any system which would give the reward of leadership to other than those who by demonstrated ability and work earn it and are entitled to it would be destructive of the principles upon which our development and our greatness are founded."

Mr. Grant, who is also president of the Susquehanna Coal Co., of Cleveland, Ohio, was in Philadelphia on what is termed as a "cross-sectional view of activities of the local Chamber of Commerce." After discoursing at length on the urgency of management, he added that, "public need, the equipment and material which capital provides and available employees will not constitute a business activity. They merely constitute a business opportunity. Unless somebody has the vision to see the opportunity and to organize it and finance

## Here's Another Mule Story

There's a mine superintendent out west who believes some mules actually think. He enters one in the "bright mule contest" now raging in these columns. Says he: "I know a mule which absolutely refused to work underground and which figured out a system of its own to enforce its refusal. When they took him down and put him to work, he always ran away the first time the driver cut him loose from a load. Then he ran to the shaft, cleaned the bottom of men by backing up threateningly at anybody who got in his way, and then jumped into the sump. This always tied up the mine until the whole bottom crew spent an hour hoisting him out. Well, sir, he did that trick every blamed time they tried to work him below. He must have had it figured out that some day they would get tired of his stopping up the whole mine that way. And he won. I tell you that mule thinks."

Next!

it and make it a reality, nothing whatever will happen, even though the opportunity exists. Business opportunities only become business realities when the remaining constituent element of business is present. That remaining constituent element is management."

## Five Companies Merged in \$2,000,000 Concern

A number of coal operators of Birmingham, Ala.; Memphis, Tenn., and Kentucky are principals in the formation of the Great Western Coal Co., a \$2,000,000 company, incorporated under the laws of Delaware. The new corporation is a consolidation of the following concerns: Hawley-McIsaac Co., Inc., Western Coal Co., Gideon Coal Co., Morris Coal Co. (all of which are stripping operations in the western part of Kentucky) and the properties of the Kershaw Coal Co. in Kentucky.

An issue of \$800,000 bonds has been sold to the Atlantic Exchange Bank & Trust Co., of Baltimore, the consolidation and sale of bonds being handled by Charles E. Rice, of the firm of Tillman, Bradley & Baldwin, of Birmingham, Ala.

Among those interested in the company are C. G. Kershaw, T. M. Porterfield, B. R. Smith and J. S. Stone, all of Birmingham; John R. Collins and R. J. Billings, of Memphis; C. R. Hawley and H. M. McIsaac, of Madisonville, Ky.

Operations of this company are located on the Illinois Central R.R. in Hopkins County, Kentucky, and on the Louisville & Nashville in Ohio County, Kentucky. The present output of these mines is on a basis of 900,000 tons annually. Steam shovels of the largest and most modern type are used in mining coal by this company.

166 Miners' Lives Lost in Mine Accidents in August; Eight Months' Total 1,628

Accidents at coal mines in the United States during August, 1924, killed 166 men, according to information received from state mine inspectors by the U. S. Bureau of Mines. The fatality rate for the month, based on an output of 41,851,000 tons of coal, was 3.97 per million tons, about 27 per cent lower than the rate of 5.46 per million tons for August, 1923. The rate for July, 1924, was 3.79. The average rate for August over a ten-year period (1914-23) was 4.17, so that the rate for August of the current year represents a reduction of about 5 per cent. The rate for bituminous mines alone for August, 1924, was 3.77 per million tons, as compared with 5.46 for August last year and 3.89 for the month during the ten years mentioned. For anthracite mines alone the August, 1924, rate was 4.94 per million tons, as against 5.41 for August last year and a ten-year average rate for August of 5.81 per million tons.

Reports for the first eight months of 1924 show that 1,628 men have been killed by accidents at the mines, as compared with 1,793 during the same months last year. The 8-months fatality rate for this year was 4.58 per million tons, as compared with 4.12 in 1923. The increased rate for 1924 was entirely in the bituminous industry and was caused by the explosions of gas and coal dust. The bituminous rate for the first eight months of 1924 was 4.40 per million tons; in 1923 it was 3.83. The anthracite rate for eight months

W. K. Field

President of the Pittsburgh Coal Co., which post he has occupied during the last fourteen years. He has been actively identified with the coal industry for more than thirty years.

in 1924 was 5.48; last year it was 5.63 for the same period.

An analysis of the causes of accidents in 1924 to the end of August, with those for the same period in 1923, shows an increased rate for gas and dust explosions in 1924, but no material change in the rates for other causes of accidents.

Refer Mine Feud in Colorado To Governor Sweet

A row, having the earmarks of a feud, between miners and mine owners near Milner, in Routt County, Colorado, has been referred to Governor Sweet by Walker Glaister, general manager of the Yampa Fuel Co. Mr. Glaister wrote the Governor that his company cannot operate its newly leased Yampa mine, in Curtis Gulch, because a railroad bridge on the spur line running from Milner to the mine was burned some time ago, he thinks by incendiaries who sought to keep the mine from operating. He said threats have been made against the mine in case operations are resumed, but that Sheriff Charles Neiman and the county commissioners do nothing. Sheriff Neiman denied this by telephone to the Governor and said that \$500 was offered for the arrest of those who destroyed the bridge.

Upon investigation Governor Sweet discovered that the mine had been leased previously to several small mining companies, all of which failed to operate it successfully, and all, on abandoning it, failed to make good their obligations to the miners to the extent of \$20,000. The Governor wrote A. J. McGuire, president of District No. 15, United Mine Workers, to take personal charge of the miners for the time being, with the idea of preventing violence. He instructed Sheriff Neiman to maintain law and order. He wrote Mr. Glaister, and W. W. Curtis, of Colorado Springs, owner of the mine, that wages due the miners must be paid.

## Moffat Tunnel Through Rockies Well Started, But Who Will Use It?

Real progress has been made in the driving of the Moffat tunnel in Colorado, which is counted on to give Routt County coal a better outlet. The tunnel, which is to be approximately six miles long under James Peak at the Continental Divide, is on the line of the Denver & Salt Lake R.R. (Moffat road), and may be used by that railroad but is being built by the state. Two bores are being driven simultaneously. An 8x8-ft. pioneer or water tunnel has been driven 4,450 ft. from the east portal and 4,150 ft. from the west portal and is thus 26 per cent finished. A total of 378 ft. of crosscuts is completed, or about one-third the total of crosscuts. Headings measuring 7½x9 ft. in advance of the main bore have been driven 4,260 ft. from the east and 2,800 ft. from the west. The railroad tunnel itself, which is to carry a single track, is finished for 1,120 ft. from the east and 480 ft. from the west portal. The loading out of rock from this work is all done by mechanical shovels.

Although the Moffat tunnel has been boomed for years as a possible great aid to the coal industry of Colorado because of the present difficulty of hauling coal out of the rich but little developed fields of Routt County, little enthusiasm over it is felt by Colorado coal men. Of course the bore, if used by the Moffat road, which is the only carrier for the region now, will eliminate more than 20 miles of heavy grades over the crest of the divide. Great difficulty has been experienced by the railroad in keeping this part of its line open in rough weather. Snow and rock slides tie up the road frequently. Also the whole route over the mountains is expensive to maintain. Curves have been so bad that derailments are common. The result has been that the Routt County shippers of coal do not always get enough cars when they need them and coal en route is often long delayed. Some of these troubles no doubt would be eliminated by the use of the tunnel by the Moffat road.

But as a matter of fact nobody knows positively that the Moffat road will lease the bore. No lease has yet been made nor any form of contract signed. There is much talk in Colorado of the possibility of the Denver & Rio Grande Western Ry. leasing or buying the Moffat road, extending it from its present western terminus at Craig, Colo., to a junction with the Salt Lake line

## Woodward Colliery Reopens After Long Layoff

With the resumption of operations at the Woodward colliery of the Glen Alden Coal Co., at Edwardsville, Pa., Oct. 1, more than 1,800 miners returned to work after a layoff of three months made necessary by a series of repairs being made to the mine. The resumption is largely due to the efforts of Rinaldo Cappellini, district president of the miners' union, who called on S. D. Dimmick, vice-president of the company, a day after the return of the latter from a European tour and induced him to consider negotiations for the resumption of operations at the Edwardsville colliery.

Several days elapsed while Mr. Dimmick conferred with the Glen Alden officials, and it was finally decided to open up the colliery and conduct the remaining repairs during the night shifts and on Sundays.

Stanley Williams has been officially appointed check docking boss at the colliery by the local mine union officials, Mr. Williams was elected to that duty by the men last July.

of the Rio Grande somewhere in Utah. This would give the Rio Grande a much shorter route from Denver to Salt Lake City. The financial embarrassments of the Rio Grande have previously made such a purchase unlikely, but the future of the road now looks brighter and a lease of the Moffat road together with the construction of a western link is a possibility.

The Union Pacific also is considered as a possible lessee or purchaser of the Moffat road. If that railroad built a link from its main line in western Wyoming south to connect with the present terminus of the Moffat road it could help develop the northwestern region of Colorado and shorten tremendously its route from Denver to Salt Lake City.

These railroad conjectures keep the nimble wits in the Colorado coal industry busy, but the actual digging of the tunnel and all the possibilities for the use of it have not started any rush of coal interests toward Routt County. In spite of the unquestioned high quality and great extent of the coal of that region and in spite of the probability that some day some good railroad will serve the region, there still remains the obstacle of high freight rates which Routt County coal is always expected to face, tunnel or no tunnel, because of the long mountainous haul. There are now 24 mines in Routt County, nearly half of which are shut down.

## Alberta Operators Not Likely To Reopen This Season

Owing to the Alberta miners' strike American coal is now in general use on the Canadian National Rys. as far as Biggar, Sask., and the prospects are that it will be supplying motive power for the trains even in Alberta before the winter. At present only two mines, at Coal Valley and Stereo, worked by non-union miners, are supplying coal to the Canadian National. The proposal to open some of the closed mines with non-union labor under police protection has been abandoned in favor of another attempt to bring the operators and miners together in a conference, but there is little hope of a settlement.

Operators of northern Alberta, it is stated, are not particularly anxious to reopen the mines, as they have lost the market for the season with little hope of regaining it at present. Alberta coal is at a disadvantage in competing in the Winnipeg and Manitoba markets with the more cheaply mined coal of Pennsylvania and the operators are disposed to continue the struggle to cut production cost. The introduction of natural gas into some of the cities and towns of northern Alberta has somewhat lessened the demand for coal, and the mines still in operation are pushing sales in other localities.

## Backers Want to Build New Indiana-Kentucky Road

Opening of a new coal field in southern Indiana which now is not penetrated by any north-and-south railroad and which contains more than 7,000,000,000 tons of coal will result from the building of the proposed new Owensboro, Rockport & Chicago Ry., between Owensboro, Ky., and Elnora, Ind., by way of a proposed new toll bridge over the Ohio River at Rockport, according to testimony witnesses gave before the Indiana Public Service Commission late in September. The total cost of the road was estimated at \$6,767,016.45. Bonds amounting to more than \$6,000,000 and stocks of \$2,500,000 are to be sold.

The railroad would be 71.9 miles long in Indiana and 12½ miles long in Kentucky, connecting with the L. & N., L. H. & St. L., and the Illinois Central railroads at Owensboro; the Southern Ry. at Rockport, Velpen and Tennyson; the B. & O. at Montgomery, and the C., M. & St. P. and E. I. & T. H. at Elnora.

## Practical Pointers For Electrical And Mechanical Men

### Tool Saves Time in Trimming Slot Insulation After Motor Is Wound

**A**FTER the coils are all in place in a newly wound armature or stator the protruding slot insulation, usually consisting of a heavy paper, must be trimmed flush with the laminations. The common method of trimming using an ordinary knife is slow, tedious, and hard on the fingers and does not always produce uniform results. With the proper tool this work is almost a pleasure, being accomplished by making successive slices by moving the tool parallel to the slots and holding it so as to slide on the laminations.

The paper-cutting tool shown in Fig. 1 has a slightly turned up point so that it slides easily over any irregularities of the laminations. The offset handle keeps the operators hand clear of the work. It is important that the cutting edge be kept quite

Fig. 1—Used in Hannastown Winding Shop of Keystone Coal & Coke Co.

This tool has an offset handle enabling the operator to cut the insulation for the full length of the slot without bumping his knuckles on the lamination.

sharp to eliminate any tendency to tear rather than cut the insulation. The material, if tool steel, and the cutting end is tempered to about the same hardness as a wood chisel.

#### DON'T BUMP YOUR KNUCKLES

A more simple form of slicing tool is illustrated in Fig. 2. It is constructed from a heavy-power hack saw blade and the handle is formed by a wrapping of ordinary friction tape. This type of tool should be at least six inches longer than the slot, so that the operators hand will not hit the end of the laminations.

In order to keep the cutting edge flush with the bottom side of the blade

Fig. 2—Used in the Library Winding Shop of the Pittsburg Coal Co.

This tool, having no offset, is made long in order that the handle will not interfere on average length slots.

Fig. 3—View of Cutting Groove

The cutting is done in the very apex of the "V" opening which is flush with the bottom surface of the tool.

it must be formed by grinding on one side only, as indicated by Fig. 3. Both forms of the tool are the same in this respect, and in each the actual cutting edge is at the end of the opening between the two prongs shown at *a*.

### Two-Motor Fan Drive Is Good in Emergencies

Continuity of service at coal mines is sometimes vital. This is especially true with mine fans. If the fan stops a relatively safe mine may quickly become a den of danger and death.

from the mine shaft, the fan is connected to a two-motor drive. Under ordinary conditions the fan is driven by a large induction motor served from an overhead power line carrying 2,200-volt alternating current. Another motor mounted on a common base plate is a direct-current unit. This motor may be supplied from a direct-current circuit which comes from the main hoisting shaft and also supplies the direct-current energy for the inside workings.

#### OLD MOTOR EARNS ITS KEEP

There are several advantages to this arrangement because practically no extra expense is involved in this duplication of equipment. The direct-current feeder does not stand idle because it supplies the coal-cutting and haulage machines. The direct-current motor is a very old type probably unsuitable for any other purpose around the mines. Consequently, if it were not placed in stand-by service it would have been sold at a loss or would be taking up space in the warehouse, rusted and out of service.

Two flexible couplings connect the two motors to a common belt drive which operates the fan. Normally the coupling on the induction motor is

#### Alternating-Current Motor of Double-Unit Drive

Ample ventilation for the motor winding is provided by setting the motors near windows and doors. This view shows the alternating-current motor which normally drives the fan.

Realizing this, the O'Gara Coal Co., at Harrisburg, Ill., has resorted to various schemes to make sure that mine fans will not stop when the usual supply of power fails to reach the driving motor.

At one fan installation, some distance

connected to the pulley shaft and the coupling on the direct-current motor is disconnected. It takes only a short time to make the coupling between the direct-current motor and the pulley shaft complete because all parts are on hand. Separate control apparatus is

How the Two Motors Are Coupled

A motor on each end of the pulley shaft makes the possibility of a shutdown reasonably remote. The power supply to the induction motor is furnished over an outside transmission line, the power for the direct-current motor is taken from a circuit inside the mines.

provided to start, stop and protect the direct-current motor when it is in operation.

### Keep Pump Impellers in Balance—It Pays

Centrifugal pumps, like alternating-current machinery, are mysterious devices to some men. Whenever anything goes wrong with one of them such workmen just throw up their hands in despair.

Strange as it may seem, a centrifugal pump is one of the simplest pieces of apparatus used in the mines. It is compact and constructed of a few simple parts, only one of which rotates.

J. F. MacWilliams, power engineer of the Pennsylvania Coal & Coke Corp., Cresson, Pa., tells us an interesting experience he had with a pump and writes as follows: "Recently we had considerable trouble with a centrifugal pump. The wearing rings would wear out in about one month. There was no apparent reason why this should happen, so the impeller was brought to the shop for inspection, a spare unit being installed in its place. The dimensions of the impeller checked quite reasonably with the manufacturer's prints, but before the impeller was returned to the mines it was placed on balance ways. This test disclosed the fact that the impeller was  $\frac{1}{2}$  lb. out of balance.

"The impeller was balanced and re-installed, seemingly improving the mining. From this experience it would seem that more attention should be given to the balance of pump impellers. If they are out of balance there is a tendency for them to swing and increase the wear on the wearing rings, and consequently the efficiency of an unbalanced impeller will be low.

"We have decided in the future to check all impellers as they come to the shop, and if found to be unbalanced they are corrected and a record of wear kept to see if the efficiency holds up better.

"It would seem that if it is important to balance other machines which operate at speeds as high as 1,750 r.p.m. it also should be important to balance pump impellers."

### Simple Test-Board for Shop

We see many kinds of test-boards in mine repair shops, varying from the elaborate and expensive factory product to the simple home-made type which in its most abbreviated form consists of nothing more than one or two lamps in

series with test leads connected to the low-voltage lighting or trolley circuit. The test-board pictured here is used by the Keystone Coal & Coke Co., of Greensburg, Pa.

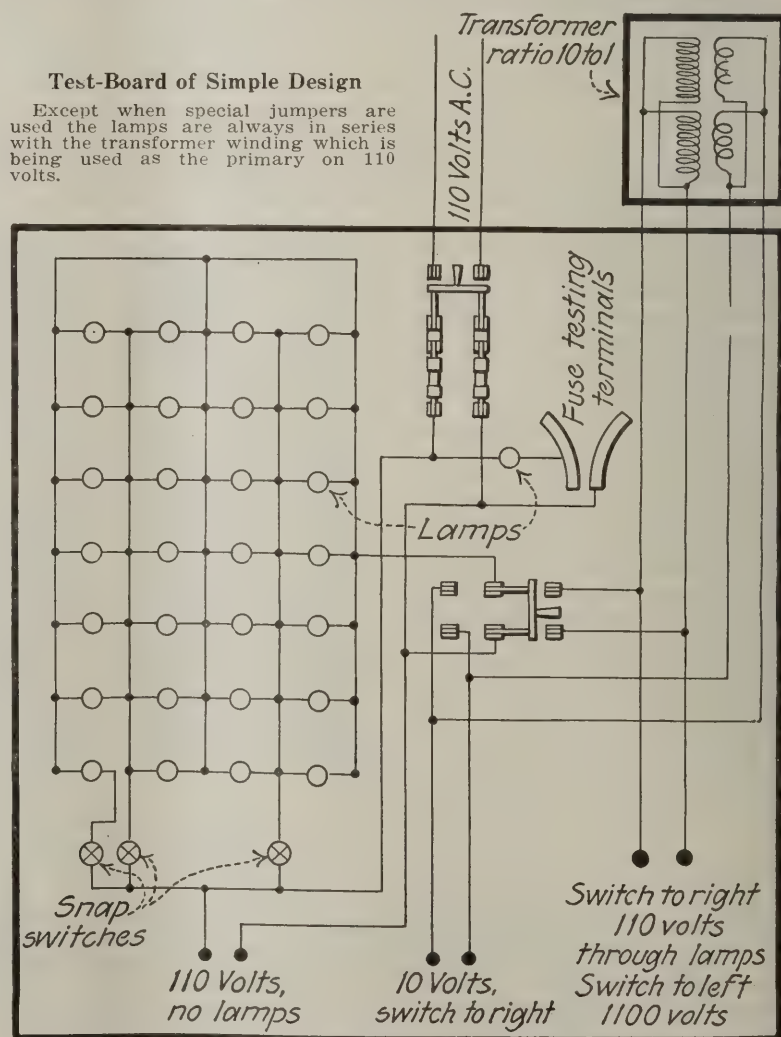

The curved copper strips are proportioned so that any ordinary size fuse is conveniently tested by touching its terminals to the copper strips and noting if the adjacent lamp lights. For other testing purposes leads are connected to any one of the three pairs of terminals seen at the bottom of the board. By manipulating the double-throw switch either 10 volts or 1,100 volts are obtained; in either case, however, the side of the transformer then serving as the primary is in series with one of the desired number of lamps as controlled by the three snap switches. When testing 250-volt direct-current armatures for grounds, with 1,100 volts, it is very desirable to limit the current in case the insulation breaks.

The 10-volt terminals often are used when making a bar-to-bar test on armatures. Low-resistant armature windings required a large current to obtain the desired intensity of sound in the telephone receiver when used in the bar-to-bar test to detect faults.

Mr. Demi, chief electrician of the Keystone Coal & Coke Co., states that this company has found this type of board very satisfactory and that several have been installed at the company's various mines.

### Test-Board of Simple Design

Except when special jumpers are used the lamps are always in series with the transformer winding which is being used as the primary on 110 volts.

# Production And the Market

## Bituminous-Coal Market Slowly Forges Ahead; Output and Prices Continue to Climb

The bituminous-coal market continued to forge ahead during the last week. The improvement, of course, is more marked in some fields than others, Baltimore, for instance, still being in the throes of the depression that descended upon the industry last spring. A most encouraging development, however, is the display of strength in the New England market, where pessimism reigned so long. Business is so brisk in western Kentucky that it is difficult to keep track of prices, they change so rapidly. In the other centers, however, the upturn is more gradual. Car supply has become a problem already in fields served by the Chesapeake & Ohio, Norfolk & Western and the Louisville & Nashville as well as in the Birmingham district.

### General Conditions Gradually Improving

While the pace of general industry is irregular the trend is definitely upward and prospects are getting better, particularly in such basic industries as iron and steel as well as textiles. A notable feature of this expansion is seen in the huge orders for equipment being placed by the railroads, \$60,000,000 having been spent for this purpose during the last month by carriers in this country.

Coal Age Index of spot prices of bituminous coal again advanced one point during the last week—its fifth successive rise—standing on Oct. 6 at 171, the corresponding price for which is \$2.07. This compares with 170 and \$2.06 respectively on Sept. 29.

Activity at Hampton Roads registered a further reaction last week, dumpings of coal for all accounts during the seven-day period ended Oct. 2 totaling 331,398 net tons, compared with 356,557 tons handled during the preceding week.

Coal movement up the lakes is holding up well despite the belief of some that it is a finished job as far as this year is concerned. Dumpings at Lake Erie ports during

the week ended Oct. 5, according to the Ore & Coal Exchange, were as follows: For cargo, 731,604 net tons; for fuel, 45,145 tons, compared with 734,246 and 39,686 tons respectively during the previous week.

Output of bituminous coal is improving steadily, the total for the week ended Sept. 27, according to the Geological Survey, being estimated at 10,189,000 net tons, an increase of 359,000 tons over the week ended Sept. 20, when 9,830,000 tons was produced, according

to revised figures. The average daily output—nearly 1,700,000 tons—is 193,000 tons less than at this time a year ago, but is slightly higher than at the same time two years ago. Anthracite output also continues to mount, the total for the week ended Sept. 27 being 1,942,000 net tons, compared with 1,851,000 tons during the previous week.

Anthracite is moving easily in most markets, though a large proportion of the business is in small orders, and prices hold firmly. Stove continues to be most in demand, but there is a better call for the other sizes also, including steam coals, No. 1 buckwheat being in particularly good shape. Production has been hampered considerably by floods at a number of mines following the heavy rains of last week.

### Midwest More Than Holds Its Own

Though there has been a lull in orders for domestic coal at Chicago, prices have not weakened, as operators are far behind in deliveries of orders accepted some time ago. All lump prices have stiffened, and this applies also on cheaper grades in the various districts. Egg prices also have stiffened to a uniform level. Dealers who are unable to get shipments on their lump orders are willing to accept 6x3-in. egg. Smaller sizes of all grades, however, are somewhat hard to move. Screenings are plentiful. Nos. 3 and 4 nut are being held on track as "no bills." Some Indiana mines are still running part time, but these are mines that usually depend on steam business.

The western Kentucky situation remains unchanged—oversold on lump, egg in fairly good demand, but smaller sizes going begging. Smokeless coals of West Virginia are readily absorbed, and the prices firm. Anthracite is coming in fairly well and is being absorbed eagerly.

In southern Illinois most mines are oversold for five or six weeks on lump and egg. Nut is beginning to move some but not to any great extent. Screenings are slow and almost impossible to move. Many mines have been idle on account of unbilled steam sizes and there seems no relief for this. The mines are averaging four days a week. Strip mines are working practically every day. Somewhat similar conditions prevail in the Duquoin field, except that

prices range 25c. lower on domestic sizes. Screenings here, as in the Carterville field, are now down to \$1.25. The Mt. Olive field has picked up notably, save that smaller sizes are hard to move in spots, being applied mostly on contract. Prices, however, are unchanged. In the Standard district there is plenty of coal moving but at hardly above production cost. Screenings are as low as 50c. and 2-in. lump is ranging around \$2.50 with 6-in. lump \$2.50@2.75 with a good demand for lump and no call for anything else. Railroad tonnage continues pretty good. Mines are getting three or four days a week.

At St. Louis the demand for domestic sizes continues good on the better grades of lump. Mt. Olive is coming into its own, while Standard is a little bit slow but it is picking up. The weather has been a little bit chilly and this has stimulated the household demand. Local wagon-load steam is showing up well but carload is slow. Mt. Olive and Carterville have advanced 25c. a ton retail. Standard has not moved up yet. Country steam is slow excepting in spots, but domestic is good for both high and low grades.

### Business Heavy in Kentucky

Operating mines in western Kentucky, with a good car supply and good labor supply, are going ahead on a full-time basis and the field as a whole is more active than for

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924			1923
	Oct. 6	Sept. 29	Sept. 22	Oct. 8
Index	171	170	169	190
Weighted average price	\$2.07	\$2.06	\$2.04	\$2.30

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

a long time past. Prices are changing rapidly, and mostly for the better, except for screenings, which are lower.

Peak prices in both the eastern and western Kentucky fields are at around \$3.50 for best block sizes. West Kentucky is quoting 75c. on screenings and east Kentucky 85c. as a minimum, but shading these prices 10c. at times to move surplus. Mine run is quoted at around \$1.35@\$1.90 in both sections, although west Kentucky isn't quoting much at under \$1.50.

Louisville retailers are meeting with a big demand for coal, and are taking a lot of fuel not only to take care of immediate deliveries but for yard stocking. This condition is also true in the rural districts, and in states to the north.

Northwest Markets Ease Along

Trade in the Northwest moves along quietly with only a fair industrial demand here and in Duluth. The Steel Corporation is bringing up plenty of coal, however, and this points to a winter of mining, which will help the docks some. Trade in the Dakotas is brisk. Pocahontas lump took a 50c. jump at the Head of the Lakes this week, bringing the dock price to \$7.50. Other bituminous prices are the same. Thirty-five cargoes, of which seven were hard coal, arrived at Duluth last week. Eleven are reported on the way, of which three are hard coal. Railroad congestion is feared, as incoming grain is already tied up.

Twin Cities consumers continue to buy coal only when they are forced to do so, but nevertheless strengthening prices have been the rule in the all-rail coals. Southern Illinois lump is firm at \$3.25; central Illinois lump, \$2.75; Indiana lump, \$3@\$3.25; western Kentucky lump, \$2.75@\$3. Dock coal prices continue to be at list, and increased prices

are suggested as likely, though the competition of all-rail coal works to hold it back. There has been something of a shift in the demand for all-rail coal, due to the 28c. increase from southern Illinois and the deferring of the increase from northern and central Illinois and from Indiana. Some of the product from Indiana and from central and northern Illinois will get into this district as against the higher cost on southern Illinois. The dock trade is working hard to gain business under the new conditions.

Coal is moving better at Milwaukee, but even so it is not brisk. Consumers are holding back, seemingly because of a lack of funds with which to put in the usual winter supplies. This is noted throughout Wisconsin and the Northwest. Dealers expect a rush when real cold weather sets in, with consequent difficulty in filling orders. The higher grades are hard to get just now, as the mines are sold up to capacity for at least six weeks. This is especially true of the Kentucky mines. Coal is coming in freely by lake. During September the receipts at Milwaukee were 397,231 tons, of which 75,431 tons were anthracite and 321,800 tons were bituminous.

Western Centers Show Vim

Heavy demand for Kansas lump has caused an advance of 50c., to \$5 a ton, on that grade. Other grades remain unchanged. Some operators are behind on deliveries of lump, but there is a slowly mounting surplus of screenings. There likewise is a strong demand for Arkansas lump. The demand for Arkansas screenings is so light that some shippers are quoting them as low as \$1.25. The circular price remains at \$2, with Arkansas semi-anthracite lump \$5.50@\$7, and mine run \$3@\$3.50. Henryetta (Okla.) lump is quoted at \$5; nut at \$4; mine run at \$3.25 and screenings at \$1.75.

Demand for domestic sizes has improved in Colorado but not to such an extent as expected, considering the small amount of coal having been taken into stock during the summer months. Working time at the mines last week averaged twenty-nine hours with only 27 per cent of the working time lost attributed to "no market." Prices remain unchanged and the present supply of labor is sufficient.

In Utah the industrial demand is light, about the only concerns buying coal being the mining and smelting companies. The domestic demand is normal for the season. Nut coal is moving slowly compared with the other sizes. Heating plants are taking slack. The car and labor situations are satisfactory, and wholesale prices remain firm. Retail prices are still unsettled with the tendency upward. Utah mines are operating around three days a week.

Ohio Markets Hold Gains

The Cincinnati market is holding up well, partly because of extra orders from northeastern Indiana, eastern and central Michigan. Lake buyers have been active, insisting on contract shipments being hurried, and some have entered the slack market, for which a drop was expected, but with these takers it has not been forced below 90c. and has ranged up to \$1.10 for good gas offerings. The principal cause for note in the high-volatile fields is a diminution of equipment, allotment being necessary on some roads. In the smokeless market there has been a vast improvement, some firms reporting full bookings for the month. Slack is still going begging at \$1.15@\$1.25 a ton.

Domestic demand has expanded at Columbus to such an extent that prices have advanced from 25 to 75c. per ton in many cases. Splints and Kentucky grades have advanced and the strength has extended to smokeless varieties. Dealers in Indiana and Michigan are coming into the market, which complicates the situation. Steam business is still dull and featureless. Buying is restricted to immediate wants and the larger users are content to buy on the open market to a large extent. Contracting has not been stimulated by the better domestic demand and screenings are exceedingly weak, owing to the larger production.

Demand for prepared sizes for domestic use is stronger at Cleveland now than at any time this year, and particularly is this true of smokeless fuels from fields to the south, the f.o.b. mine prices on all of which have advanced somewhat during the past two weeks. Steam coal also is in more consistent demand. Output in the eastern Ohio No. 8 field is now larger than at any time since February. There have been some temporary car shortages in eastern Ohio.

### Gradual Gain at Pittsburgh

Demand at Pittsburgh shows a slight further increase. The district is now working at about 50 per cent against scarcely 20 per cent in June. Industrial and railroad consumption has increased somewhat and the domestic trade has developed, though it is hardly up to normal for the time of year. Steam slack continues weak, but gas slack has stiffened, with heavier demand for the better grades, and is quotable at \$1.15@1.35 according to quality against \$1.10@1.20 a week ago. Otherwise prices are unchanged.

Further slight gains are being made in the central Pennsylvania field. Loadings for the week ending Sept. 27 were 13,998 cars, against 13,860 the week previous.

Trade is exceedingly dull at Buffalo. Resumption of operations in various mines which have been able to make lower wage agreements with their miners has added to the output and hurt an already overloaded market. In consequence slack has lost all its recent advance.

With the approach of winter the Toronto market is gradually improving. Householders are laying in supplies and a slight improvement in the industrial situation has resulted in an increased demand for soft coal. Both soft and hard coal are coming in in plentiful quantities, and there is no possibility of a shortage of either for a long while to come.

### New England Market Gains in Strength

Further appreciation has occurred in prices in the tidewater bituminous situation at Boston. For standard grade New River and Pocahontas \$5.35 gross ton on cars is as low as has been named the past week which compares with \$5.25 a week ago and \$5.15 a fortnight previous. Some shippers have not been open to orders at \$5.35, demanding at least \$5.40 and quite a fair tonnage has been booked. Some small lot business has been taken at \$5.45 and at least one sale is noted at \$5.50. The advance in spot f.o.b. prices at the Southern piers is principally responsible for this increase.

Rather too plentiful receipts at Providence the past week have prevented any advance in prices but the level has been well maintained at \$5.35@5.40 gross ton on cars for standard grade coal.

One or two shippers have managed to pick up some more orders on Pennsylvania steam coal the past week, but generally speaking, the all-rail phase of the market remains very quiet. Prices remain about the same, the range for business in New England being \$2@2.50 net ton, mines.

A noticeable feature in the market has been a further increase in the demand for coke, particularly heating coke, and fair sales of Connellsville crushed and sized are noted at \$9.25@9.75 net ton delivered.

### Quality Coals Move Well in Atlantic Markets

For the first time since early summer some of the railroads are taking full coal requirements in the New York market. This together with a better demand from along the line has stiffened the market, prices, however, remaining steady. Many producers of high-class coals are sold up for some time to come. The cheaper coals are not moving as easily. The tidewater situation is in better shape. With demand stronger along the line shippers are not sending heavy shipments to tidewater, finding they can obtain better prices from inland dealers.

Slight improvement continues at Philadelphia. Inquiries are fairly numerous and the tonnage reaching this market is slowly increasing. Prices do not move upward, however, save in isolated instances. Most buying continues to be

centered on coal of Pool 9 grades, as the consumer for the most part wants a good article when he does buy. In the gas-coal market there is freer production of slack, which is in good demand by cement plants. The B. & O. car shortage seems to have passed. The tide market is unchanged.

The flat condition of the Baltimore market is a disappointment to coal men who had expected a boost in trading with the appearance of autumn. Industrial demand is light, as general business is at comparatively low ebb. While the export situation is behind other years, foreign shipments increased in September over the previous month.

Some cool weather at Birmingham boosted domestic trade decidedly, inquiry gaining strength and a substantial tonnage being booked for points throughout the territory. Medium grades are in better demand. The steam market also has improved. Quotations on steam coal are firm with some advance in domestic grades for October delivery. There has been some improvement in the working schedule of the larger commercial and domestic mines. Gondolas have been in short supply.

### Anthracite Moving Easily

Anthracite is moving freely at New York. Stove continues to be the most wanted size with egg much easier. Chestnut is plentiful but is far from being a drug on the market. Prices hold firm. Dealers are dependent to a considerable extent upon small orders but are well supplied to take care of any rush that may come. Pea is moving slowly. No. 1 buckwheat is in good shape, the better grades bringing close to \$3. Rice and barley are in fair demand.

The Philadelphia anthracite trade has been greatly unsettled by the heavy rains and floods throughout the entire region, which checked the industry almost in its entirety for several days. The retail trade continues fair but has not progressed as well as expected. The state of the retail trade is reflected in the varying prices offered. Buckwheat is improving, but rice and barley are quite slow.

Demand for anthracite at Baltimore is only moderate. There are fair stocks in yards, but as many homes have empty cellars the next few weeks probably will see much more active conditions. Several boats have just been chartered to bring British anthracite to this city.

In the Boston market the demand for straight stove is such that \$10 50 gross ton mines is readily paid, but egg is not wanted and consequently is quoted at \$8.75. The steam sizes also have slowed up and No. 1 buckwheat is offered at \$2.25 without results.

Anthracite is moving better at Buffalo. The quantity in consumers' cellars is less than usual, but it is difficult to get them to buy. Some large consumers are trying smokeless coal and practically everybody is using natural gas.

The Connellsville coke market presents a slightly weaker tone, though there is no quotable decline in prices. It appears that while in August production and consumption were closely balanced, some operators obtaining additional business since then have blown in more ovens than needed merely to take care of the additional business, so that there may be some surpluses to work off.

Foreign Market

And Export News

British Coal Market Weakens in Face of

Keen European Competition

All sections of the Welsh coal market are in a very weak condition, business is diminishing and conditions generally seem to have gone from bad to worse. It has been decided to close down more pits, and a large proportion of the remaining collieries are working not more than three or four days per week. In some cases, notably at the Mardy Pit, Rhymney, the miners have agreed to revised operating conditions, and a threatened shutdown has been averted. In many instances the miners are co-operating with the owners in their endeavors to maintain the pits in operation, a case in point being the Big Pit, Blaenavon, where the miners have agreed to double shifts and other conditions. Competition is being felt keenly, and the operators everywhere are inclining to the view that revised conditions for the industry are necessary, either in the form of double shifts or the extension of the working day from seven to eight hours.

The general demand is somewhat restricted; business with France is slow and orders from Italy are only a fraction of normal. South American business is practically stagnant. There is a fair request for the best classes of dry steam coals owing to the scarcity of anthracite, but other descriptions are overstocked and irregular.

The Newcastle market seems steadier, particularly in steam coals. Prompt business is slow and export inquiry is so low as to be negligible. Twenty pits are idle in Durham and there are 6,000 miners out of work; in the majority of cases the pits are operating not more than three shifts per week.

Output by British collieries during the week ended Sept. 20, a cable to *Coal Age* states, was 5,135,000 tons, according to the official reports. This compares with 4,907,000 tons produced during the week ended Sept 13.

Lull in French Coal Market

Extends to Domestic Fuel

The French coal market is stationary. Output is steadily mounting in the Nord and Pas-de-Calais, the average deficiency in daily production when compared with 1913 now being only 7,000 tons.

The demand for industrial coals is quiet, but stocks are not heavy. Competition of British prices is not keen as yet.

Deliveries of house coals are somewhat lower. The prices for October have been officially established at the same levels as for September, with the exception of ovoids, which have been reduced to 117.20 fr. net. Belgian prices for export to France also are unchanged, ovoids alone being reduced to 107 French francs net.

Imports from South Wales are normal again.

German tenders of coal on the free market continue large, but deliveries still fail to keep pace with the offers.

Rail traffic has improved on the northern lines, but on the State Railway system at Rouen the situation is still bad, as only 50 to 60 per cent of the requirements are covered, and very often the product cannot be used because of deterioration. Canal freight remains at 22 fr. Béthune-Paris.

Firm Tone at Hampton Roads;

Outlook Brighter

Business at Hampton Roads shows little change from last week, being fair in all sections, with coastwise and bunker trade responsible for the bulk of the business. The market remains at about the same point and prospects continue to brighten.

Accumulations at the piers are not so heavy and movement from the mines has decreased to some extent. Foreign business is confined largely to

Italy and Brazil, with scattered shipments elsewhere.

The tone of the market is strong. Domestic business is improving rapidly, with anthracite strengthening, quoted at \$15 delivered, an increase of 50c. The best Pocahontas coal is quoted delivered at \$10.

## News Items From Field and Trade

### COLORADO

J. A. Halbert has purchased the coal mine of the Joerger Fuel Co., at Trinidad, and plans to make extensive improvements.

During the month of August a total of 701,359 tons of coal was mined in Colorado compared with 750,221 tons mined in August, 1923, bringing the total production for the first eight months of this year up to 6,285,781 tons compared with 6,479,351 tons mined during the same period last year. So far this year the number of days worked per mine in the state is 111.2. The total decrease in the production of coal during the first eight months of this year as compared with the corresponding period in 1923 has been 193,570 tons. During August 10,768 men were employed at the mines.

### ILLINOIS

W. H. Riester has been appointed general sales agent for Donk Bros. Coal & Coke Co. at St. Louis, Mo., effective Sept. 23. Twenty-five years ago on July 1 he entered this company's employ as weigh master in one of its retail yards.

H. Clarence Bean, of the Sterling-Midland Coal Co., has been transferred from Duquoin, where he was connected with the operation of the Jewel Coal & Mining Co., of that place, to Evansville, Ind., where he will be connected with the company's affairs.

The Valley View mine near Rock Island, owned by Sackville & Wynn, opened the middle of September with about 35 employees after having been down since last February.

P. H. Greenlaw, formerly in charge of statistics for the Fifth and Ninth Districts Operators' Association in Illinois, is now with the Southern Coal, Coke & Mining Co., of St. Louis, handling problems of public and employee relations. He gets out an employees' magazine which will be named in October by the employees. August and September issues have already appeared.

Rock Island County recently awarded a contract to the Rock Island Fuel Co. to furnish between 600 and 700 tons of coal to the county buildings at \$6.04 a ton until Sept. 25 and 25c. per ton higher after that date. This is a much lower price than last year. There were six bidders in the field. Saline County coal will be used.

Much railroad activity is centered around Orient mines Nos. 1 and 2, at Orient, near West Frankfort, and with the completion of two switches a total

of four roads will serve these two large coal plants. The four roads are the Illinois Central, the Chicago, Burlington & Quincy, the Chicago & Eastern Illinois and the Missouri Pacific. Mine No. 1 holds the world's record for hoisting from a single shaft in eight hours time, but the new Mine No. 2, where a skip hoist went into service Sept. 12, is expected to exceed the former when fully developed.

### INDIANA

F. J. Rawson and James G. McCarty, of the U. S. Bureau of Standards, are spending about a month in Vigo County, in research work on coal-mine tipples scales. They have nothing to do with the accuracy of the scales other than to recommend to the operators the best method to correct causes of error. They first made a trip through this vicinity in 1921 and another in 1923. They make reports to Washington from which bulletins are compiled giving information as to the best type of scale to install in a particular type of tipples.

Orders have been received at the Ingle No. 8 mine, at Petersburg, owned by the Ingle Coal Co., to clean up the mine preparatory to reopening at once. The mine, which is the largest of the Ingle system in Pike County and which gives employment to 350 miners, closed down nine months ago. It is connected with the Southern Ry. by an eight-mile switch, but arrangements are being made to connect the mine with the Big Four R.R. system by building a switch to the new railroad recently constructed by the Gray brothers of Evansville to their new stripping mines at Simtown, two miles south of Arthur. Less than two miles of track will have to be laid to connect the big Ingle No. 8 mine with the Big Four.

### KANSAS

Mine No. 18 of the Sheridan Coal Co., near Pittsburg, has been reopened.

The Missouri Pacific has put in operation two new through coal trains from Pittsburg to Kansas City, Mo., giving one-day service from the Pittsburg field to the Kansas City market. The move was made necessary by increasing coal shipments, the road announced.

A steel tipples will be installed by the Pittsburg Block Coal Co. at its mine near Dunkirk.

William Bogartz, in announcing his candidacy for re-election as president of the United Mine Workers of District 14, states that he has been unable

to carry out the policies he had mapped out upon entering office. "I encountered opposition from some of the rank and file and I did not have a working majority on the district executive board," he said in a published statement. Secretary H. W. Burr also has come out for re-election. Both have opposition. The number of candidates for district offices is unprecedented. Interest still centers on whether Alexander Howat will enter the race for president and whether the international Board will attempt to bar him as ineligible.

The Crowe Coal Co. has reopened its mines Nos. 15 and 21, in the Pittsburg field.

Leon Besson, state mine inspector, and W. D. Ryan, Kansas City, safety commissioner for the Bureau of Mines, called miners and operators for a meeting Oct. 1 to revive interest in mine-rescue work and begin arrangements for a Kansas safety meet in 1925. An intensive training campaign for the miners of the state will be launched immediately, training having become disorganized during a long period of mining inactivity. Practically all mines are again in operation and it is proposed to effect a safety organization at each one.

A new type steel conveyor tipples, the first such conveyor and the fourth steel tipples of any kind in the Kansas field, has been installed by the Dunkirk Coal Co. at its steam-shovel mine a mile west of Mulberry. Representatives of fifteen operating companies watched a test of the apparatus Sept. 29. A platform upon which may be driven wagons bringing coal from the pit, is installed a short distance from the railroad spur. A balance arrangement allows the rear end of the wagon to be lowered so that the load slips into a hopper beneath the platform. Here the conveyor belt picks it up and carries it to the top of the gravity screening and loading chute which makes lump and a smaller size known in the field as "nut run." The only other steel tipples in the district are at two shaft mines of the Sheridan Coal Co. and one shaft mine of the Katy Coal Co.

### KENTUCKY

The Peerless-Elkhorn Coal Co., Justell, Ky., has under development 1,000 acres of coal land, and will have daily capacity of 800 tons. F. G. Hutton, 150 E. Broad St., Columbus, O., is president.

James B. Torbert, formerly of the Phoenix Mine, near Drakesboro, who sold out in western Kentucky a

couple of years ago, is president of the new Harlan-Wallins Coal Co., which will own and operate the former plant of the Wallins Creek Collieries Co., in the Harlan field. Banks of Nashville, Tenn., are now offering a \$600,000 issue of 7 per cent gold bonds of the new company, to be used in the financing of the proposition.

The Cumberland Straight Creek Coal Co., of Pineville, will rebuild its tippie which was recently destroyed by fire, with a loss estimated at \$100,000. This tippie is located at Logan's Switch.

The Ulva Coal Co., Ulva, will let the contract at once for erection of a store building to replace the structure recently destroyed by fire, with a loss of \$10,000.

Another tippie has been burned in western Kentucky. This one belonged to the Old Hickory Coal Co., four miles out from Providence, in Webster County. The loss was about \$15,000, partly insured. The fire is believed to have been of incendiary origin.

It was reported from Whitesburg, on Sept. 21, that the Gorman-Pursiful Coal Co. would start operating a new mining plant at Sandlick within a few days, the plant starting off with a daily loading capacity of fifteen to twenty cars.

## MISSOURI

The Kansas City Midland Coal Mining Co. has reopened its 800-ton mine at Novinger.

The Walton Coal Co., of Higby, has sold its mine and equipment to a group of fifty miners who will operate it co-operatively. The mine is rated at 500 tons. The company also leased its coal lands to the miners on a royalty basis for all coal mined.

## NEW YORK

The Iroquois Gas Corporation, of Buffalo, will complete its byproduct coke plant at Winchester, near Buffalo in time to add daily 13,000,000 cu.ft. of gas to the city supply next winter. This ought to add 12,000 to 15,000 consumer families to the company's list, who would otherwise need to burn coal.

Robert H. Burrows and William R. McTurk have retired from the firm of W. A. Marshall & Co., New York City, after fourteen years' service as officers and directors. To fill the vacancies caused by their retirement John D. Kline and Raymond Havemeyer have been chosen as directors and vice-

presidents. C. W. Sandford and G. B. Talbot, formerly in business together, have joined the sales organization of the company.

## OHIO

Fire of undetermined origin destroyed the coal tippie and all equipment at mine No. 402 of the Sunday Creek Coal Co., at Santoy, recently at a loss of \$200,000. The tippie, which was electrically operated, was known as the best equipped plant in Ohio. County officials are investigating the fire, which will throw more than 400 men out of employment. It was one of the few mines in this section that was operating full time.

"Buy Ohio coal—There is none better," is the legend ordered by Governor Donahy to be printed on a large block of coal weighing approximately 2,400 lb., which has been placed in front of the north-side approach to the State House at Columbus. The huge block of coal was sent from the Massillon district and was exhibited at the State Fair by a Massillon coal company. The company presented the block to the Governor. It was received at the State House recently, carefully crated.

First-aid training among miners in Ohio will depend entirely upon state inspectors of the mine division and use of Ohio's mine-rescue trucks and car, declared Jerome Watson, when he explained to Herman R. Witter, industrial relations director, that the U. S. Bureau of Mines rescue car stationed at Columbus had been withdrawn from service in Ohio for three months. Ohio is planning for a great first-aid and safety meet soon, such as was held Aug. 15 at Bellaire, Belmont County. The government has aided in this training, but such work is being carried on in Kentucky and the use of the Ohio car of the federal mine department is required there.

## OKLAHOMA

The Pine Mountain Coal Co., of Heavener, Okla., has increased its capital from \$65,000 to \$250,000, and will build an entirely new plant, and install new machinery.

John Patterson, the 70-year old superintendent of the Kali-Inla Coal Co.'s mine at Cambria, Latimer County, claims to be the oldest active miner in the state. He began working in the mines in Scotland when he was 10 years old. He has worked in southeastern Oklahoma for 26 years. He it was who

met the several hundred union miners from an adjoining county who marched to Cambria a few weeks ago, intent on stopping the non-union operations. Alone and unarmed, Patterson parleyed with the leaders of the union "army," and as a result, threatened bloodshed was averted.

Oklahoma's coal production was 1,991,733 tons in the fiscal year ending last June 30, as against 1,945,294 tons in 1922-23 and 2,578,005 tons in 1921-22. The figures are from the annual report of Chief State Mine Inspector Ed Boyle. Coal mined, by grades, included 392,390 tons of lump, 106,622 tons of nut, 299,864 tons of pea and slack. There were 114 individual mines in operation in the state in 1923-24, the report shows.

As the result of recent renewed firing on state guardsmen patrolling the open-shop mine district of Latimer County, Adjutant General Baird H. Markham has reconsidered his intention to withdraw his troops. They will be left on the scene indefinitely. The guards stationed in the district have machine guns at the plant of each mine. Eight mines are now operating on a non-union basis, with 400 men employed at the 1917 wage scale of the United Mine Workers. A number of additional mines will reopen in the McAlester district early in October, all announcing that they will pay the 1917 bituminous scale. Two hundred men have been put to work in Creek mine No. 1 of the Crowe Coal Co., in the Henryetta field. This makes a total of 20 mines now operating in this field and at least 10 more are making plans to reopen during October.

## PENNSYLVANIA

The Superior-Connellsville Coal & Coke Co., of which George Whyel of Uniontown, Pa., is president, recently sold 202 acres of coal land at Simpson Station, near Brownsville, to Columbus R. Porter, of Brownsville, for \$370,000. The property sold was purchased from Mr. Porter in 1919 and adjoins the Superior mine operated by the above named company. The coal is in the Pittsburgh seam.

The balance sheet of the Glen Alden Coal Co., as of Dec. 31, recently issued, shows total assets of \$29,654,283, including \$9,887,669 in securities, \$4,378,302 in coal on hand, and \$9,209,413 in accounts receivable. Accounts payable amounted to \$6,355,481 and the surplus was \$4,966,766.

Business in the Connellsville coke region is picking up. The Hillman Coal & Coke Co., of Pittsburgh, Pa., resumed operations Sept. 25 at the Tower Hill No. 2 mine near Republic, after having been idle there for nearly a year. The H. C. Frick Coke Co., subsidiary of the United States Steel Corporation, has increased operations at the Collier and York Run plants and fired 100 additional beehive ovens at scattered operating plants.

The Glen Alden Coal Co. has mapped out extensive plans for a tree-planting program which will get under way in the spring of 1925. The company has much idle land which can be used for the future production of mine timbers and the work now contemplated will produce

### A New Kentucky Tippie

This steel structure has just been put into service by the Southern Mining Co. at Black Snake, Ky. It stands at the bottom of a steep tramway.

a forest growth in the years to come. Huge tracts of forest land on the West Mountain, just beyond the city limits are to be the scene of the initial tree-planting operations of the Glen Alden company. Years ago this land was the location of heavy stands of timber and the program now decided upon by the coal company gives promise of a reproduction of that growth within a quarter of a century. Forty thousand trees are to be set out by the company.

The Peabody Coal Co., of Chicago, is negotiating for the purchase of the No. 6 colliery of the Pennsylvania Coal Co., at Pittston, it is reported from authentic sources. Recently representatives of the Chicago interests visited the colliery and made a survey of conditions and equipment. At present the colliery is idle due to a strike, called without sanction of the district office of the United Mine Workers, because of alleged inequalities in wage rates in a section of the mine.

Fire, raging for several days in the Oakmont mine of the Hillman Coal & Coke Co., at Barking Station, near New Kensington, was brought under control Sept. 16 by members of the Pittsburgh station of the U. S. Bureau of Mines following the erection of brick walls. Operations in the mine were suspended when the blaze, about 200 ft. below the surface of the mine, threatened to assume serious proportions. Officials of the company said they would be unable to estimate the damage until an investigation had been made.

New officers named by the executive committee of the Hazleton Mining Institute are Commissioner James Harlor, president; D. E. Keller, superintendent of the Harwood Coal Co., vice-president; S. W. Smith, secretary-treasurer. It was decided to hold the annual banquet on Oct. 28, if suitable arrangements can be made.

The equity action in which the Philadelphia & Reading Coal & Iron Co., the New York Midd Fields Coal & Railroad Co. and the City of Philadelphia, trustee under the will of Stephen Girard, against the county commissioners of Columbia County, seeking a reduction in the valuation of property by the commissioners, has been continued until Dec. 1.

## TENNESSEE

The Connellsville Coal & Coke Co., Connellsville, Pa., of which D. B. Northrup is president, is reported to have purchased 8,000 acres of coal land from the Waldensia Coal Co., Waldensia, and 1,200 acres from the Missouri Coal & Land Co.

## UTAH

Application to increase the minimum weights for loading coal cars has been filed with the Public Utilities Commission by the Denver & Rio Grande Western, the Bingham & Garfield, the Utah Ry., the Utah Terminal Co. and the Carbon County Ry. The minimum weight is now 40,000 lb., but this is obsolete, for the reason that there is now no standard gage equipment used for the transportation of coal with a

capacity so small as 40,000 lb., the petition sets out. The petitioners state that if they are granted permission to make the desired changes, uniformity will be obtained in coal tariffs and the minimum-weight rule will be the same in Utah as is applicable from Utah mines to interstate points in Nevada, California and other Western states. It is suggested that for cars of the marked capacity of 50,000 lb. the minimum weight be 48,000 lb.; for cars of 60,000 lb., 58,000 lb.; for cars of 80,000 lb., 60,000 lb.; and for cars of the marked capacity of 100,000 lb., 80,000 pounds.

## WEST VIRGINIA

A new tipple is being built and other improvements made at the plant of the Chaplin Collieries Co., on Scott's Run, preparatory to resuming operations on an open-shop basis.

The White Rose Coal Co. has disposed of its stripping operation near Viropa, Clay District, Harrison County, for \$112,500. The property includes about thirty acres of coal, steam shovels, locomotives and other equipment. The Walton Coal Co., which is the purchaser, is understood to be an organization of New York capitalists. Thirty thousand dollars was paid in cash, the balance being secured by a deed of trust.

Efforts to extinguish a fire in the new Lincoln mine of the Lorain Coal & Dock Co. have proved unsuccessful and state inspectors have given up the fight for the time being and that portion of the mine where the coal is on fire will be sealed up again. The fire broke out on Aug. 22 and at that time a section of the mine was sealed in an effort to smother the blaze. But at the end of two weeks it was found that the fire had spread. It was decided after resealing a section of the mine to permit operations on a 60 per cent basis and work was resumed on that basis on Sept. 22. The miners will work in such sections of the mine as have not been affected by the fire.

## CANADA

At a special general meeting of preferred shareholders of the Dominion Coal Co. held in Montreal recently consent to the proposal to create a \$15,000,000 mortgage, as required on the company's property, was given and the meeting authorized the mortgage.

The Princeton (B. C.) Colliery Co. is sinking a new shaft on the town site of Princeton, B. C., and is preparing for the construction of a new colliery.

Charles Graham has taken over the management of No. 5 Mine, Comox, Canadian Collieries (D), Ltd.

Dr. R. L. Rutherford, of the Canadian Geological Survey, has returned after a season in Northwestern Canada from the Brazeau to the Athabasca Rivers. This year's work will supplement that of the two past years, the survey now having been completed from the North Saskatchewan to the Athabasca. Dr. J. A. Allen, under whose supervision the survey has been made, says that a geological map will be prepared similar

to that already made of Alberta coal fields. Another party under J. O. Sanderson has been continuing work in the Drumheller coal field. It is said that the seams of the Carbon, Three Hills, Trochu, Big Valley and Sheerness country are quite similar to those of the Drumheller district.

## Industrial Notes

Zeb Stafford, formerly with the Higrade Oil & Gas Co., at Logan, W. Va., has severed his connection with that company and is now representing the **Hulbert Oil & Grease Co.**, of Philadelphia, in the Logan district.

The **Continental Car Co.** of America, Louisville, makers of mine cars, and the **Kentucky Wagon Mfg. Co.**, of the same place, are merging. The car company has moved offices to the wagon company plant.

**C. L. Berger & Sons, Inc.**, of Boston, Mass., makers of engineering and surveying instruments, have appointed the **New York Blue Print Paper Co.**, 102 Reade Street, New York City, exclusive export agents for Latin America; this in addition to the exclusive agency for New York and New Jersey previously allotted.

The **Ohio Brass Co.** has moved its Philadelphia office from the Witherspoon Building to 1404 Packard Building, at 15th and Chestnut Streets.

**Frank A. Wilch** who has been associated with the Cleveland office of the **Triumph Electric Co.**, has been placed in charge of that territory. He succeeds **Edward S. Ford**.

**B. N. Broido** who has been doing special consulting work for **The Superheater Co.**, of New York and Chicago, recently was appointed chief engineer of the industrial department of the company.

The **Dings Magnetic Separator Co.** announces that **H. M. Gassman**, who handles Dings magnetic separators in Birmingham, Ala., has moved to a new office at 513 N. 21st St.

At the annual stockholders' meeting of the **Allison Coupon Co.**, of Indianapolis, Ind., a reorganization of the management was effected with the election of **M. J. Allison** as president, **James A. Allison** as secretary, **J. S. Berryhill** as treasurer and **John H. Allison** as general manager.

## Publications Received

**First Annual Report, Department of Labor, Tennessee, 1923.** Pp. 174; 6x9 in.; illustrated. Includes reports of Divisions of Fire Prevention, Mines, Workshop and Factory, Workmen's Compensation and Hotels.

**Bituminous Coal Losses and Mining Methods in Pennsylvania, Including Thickness, Character and Reserves of Coal,** by **James D. Sisler.** Topographic and Geologic Survey, Dept. of Forests and Waters, Harrisburg, Pa. Bulletin M 4. Pp. 216; 6x9 in.; illustrated.

**The Property Owner's Handbook** is the title of a 32-pp. booklet issued by the **American Appraisal Co.**, Milwaukee, Wis. Constitutes a collection of suggestions which anyone responsible for the management of property will find of interest.

**Annual Report of the Mineral Production of Canada During the Calendar Year 1922.** Dominion Bureau of Statistics. Mining, Metallurgical and Chemical Branch, Ottawa, Canada. Pp. 228; 6x9 in.; charts and tables.

**The Deep River Coal Field of North Carolina,** by **Marius R. Campbell** and **Kent W. Kimball.** North Carolina Geological and Economic Survey, Chapel Hill, N. C. Bulletin No. 33. Pp. 95; 6x9 in.; illustrated. Covers results of examination by geologists of the U. S. Geological Survey co-operating with the North Carolina Geological and Economic Survey.

**Annual Report of Coal-Mine Inspection and Mine-Rescue Departments, Kansas, 1923.** Court of Industrial Relations, Topeka, Kan. Pp. 149; 6x9 in.; tables.

## Traffic

### Want Freight Rates Favorable To Kansas Coal

F. J. Bannister, president of the Kansas City Chamber of Commerce, and other officials of that organization, in a conference, Sept. 18, with the Pittsburg (Kan.) Chamber of Commerce, declared they will in the future do their utmost to bring about adjustment of coal freight rates into Kansas City which will be favorable to Kansas coal. Mr. Bannister said that the traffic department of the Kansas City Chamber in working for lower Illinois coal rates in the past had to a degree overlooked the effect upon the mining industry in the Pittsburg field, which is regarded as a part of Kansas City's immediate trade territory.

Pittsburg men had pointed out to the visitors that it is directly to the benefit of Kansas City's business to promote the industrial prosperity of a population of 150,000 persons within a radius of 150 miles of that city. Illinois coal has been Kansas' stiffest competitor for the Kansas City market. Through freight rates Illinois has been gaining in the race, Kansas operators say. A concerted effort is now being made to convince Kansas City business men that southeastern Kansas coal mining is a "home industry" so far as they are concerned. One coal company is conducting an extensive advertising campaign in the Kansas City newspapers to emphasize this appeal.

### Allow 25c. Ton for Transfer Of Bunker Coal

An allowance of 25c. a ton for transferring bunker coal from cars to vessels at New Orleans was found reasonable Oct. 2 by the Interstate Commerce Commission.

The ruling was made in the case of the New Orleans Coal & Bisso Towboat Co. against the Louisville & Nashville. The rail carrier allowed only 11c. for the services but it said it was willing to make a retroactive allowance of 25c.

The commission said it would order the carrier to make good the difference of 14c. a ton for each ton handled.

### Charges Unequal Share of Cars

The Francisco Mining Co., of Chicago, has attacked the equity of coal-car distribution at Francisco in September, 1922, and asked damages in the sum of \$100,000, caused by the failure to deliver cars in the same proportion as to other mines in the vicinity.

## New Companies

The Eureka Coal Co. has been incorporated in St. Louis, Mo., with a capital stock of \$50,000, by W. J. Miller, J. M. Whelan, 4222 W. Pine Street, and L. M. Steed.

The Royalton Coal Co., capital \$10,000, has been incorporated in St. Louis, Mo., with H. H. Taylor president and Jesse Irwin Taylor secretary.

The Lenox Coal Co. has been incorporated in Frankfort, Ky., by Clay Hunley, H. M. Collins and others.

The Walton Coal Mining Co. has been organized to operate in Harrison County, West Virginia. Capitalized at \$100,000, the company is to have its general offices at Clarksburg, W. Va. Having an active part in the organization of the new company was Daniel Howard, one of the leading operators of the Harrison County field. Associated with him in the new company are C. F. Yates, C. C. Starkey, C. B. Johnson and Margaret Heitz, all of Clarksburg.

The Anchor Coal Co., Carbon Hills, Ohio, has been incorporated with a capital of \$10,000 to operate coal mines and sell coal and coke. Incorporators are I. W. Achauer, W. R. Saunder, John Saunders, John Dicken and C. Cee.

The Hill-Crest Coal Co., Fourth & Market Sts., Steubenville, Ohio, has been chartered with an authorized capital of \$50,000 to mine and sell coal. Rosa C. Anderson, Fred A. Stone, Robert J. Peterson, William E. Matlack and Carl E. Anderson are the incorporators.

The Blue Valley Coal Corporation, Madisonville, capital \$20,000, has been incorporated by H. H. Coil, F. E. Coil and J. A. Jonson to handle mine operations. The Coil family has been well known in western Kentucky coal developments for years.

The Millville Coal Co., Salem, Ohio, has been incorporated with a capital of \$25,000 to mine and sell coal. The incorporators are C. A. McKinley, W. L. Petlit, H. L. McCarty, Homer H. Hickling and Roscoe Nye.

The Beaver Coal Co., Swansea, Ill., has been incorporated with capital of \$25,000 to do a general coal mining business. The incorporators are A. C. Danielson, Theodore Sirene and Albert G. Ziesk. The company is served by the Louisville & Nashville R.R.

The Solar Coal Co., Belleville, Ill., has been incorporated with capital of \$180,000 to conduct strip-mine operations near Lemenston. The incorporators are W. C. Wolf, Robert White, Samuel White, Frank Sergeant, Albert L. Klee, John Macke and John L. White.

The T. H. Cameron Fuel Co., Ltd., has been incorporated with \$250,000 capital and head office in Montreal, Canada, to mine, import and deal in coal, by Chilton G. Heward, Henry M. Hague, H. W. Shearer and others.

The Highland Coal & Mining Co., with offices in the Safety Building, Rock Island, Ill., has been incorporated with capital of \$25,000. The company will develop a mine on the farm of William M. Ferry, located approximately two miles from Moline, on what is known as the Highlands. Preparations are being made to sink the shaft, which will be completed within the next month. The shares in the company are owned largely by Rock Island and Moline people.

## Coming Meetings

National Coal Association. Board of Directors' meeting, 9.30 a.m. Oct. 10, Washington Hotel, Washington, D. C. Open to association members and those interested. Executive Secretary, H. L. Gandy, Washington, D. C.

American Institute of Mining and Metallurgical Engineers. Fall meeting, Birmingham, Ala., Oct. 13-15. Secretary, F. F. Sharpless, 29 West 39th St., New York City.

American Institute of Electrical Engineers. Fall convention, Pasadena, Calif., Oct. 13-17. Secretary, F. L. Hutchinson, 29 West 39th St., New York City.

American Gas Association. Sixth annual convention and exhibition, Steel Pier, Atlantic City, N. J., Oct. 13-17. Secretary, Alexander Forward, 342 Madison Ave., New York City.

Canadian Institute of Mining and Metallurgy. Sixth annual Western Meeting, Oct. 16-18, Blairmore, Alta., Can. Secretary, Moses Johnson, Blairmore, Alta., Can.

Illinois Mining Institute. Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

West Virginia Coal Mining Institute. Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

Coal Mining Institute of America. Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 909 Chamber of Commerce Bldg., Pittsburgh, Pa.

West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers. Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

## New Equipment

### Welding Generator

The Allan Manufacturing & Welding Co., 726 Washington St., Buffalo, recently developed and placed on the market a 120-cycle arc-welding generator suitable for any power installation. The armature is built up on a large-diameter shaft and is carried on two ball bearings. An extension of the shaft carries the exciter armature, the frame of which is cast integral with one end bell. The exciter is eliminated where direct current is available.

The 4-kw. size has a range of 50

### Welding Equipment and Control

Almost any current value up to the full capacity of this apparatus makes it suitable for all kinds of welding or repair work.

amp. to 200 amp. continuous output, with an unlimited number of steps between these limits. With this new generator great ease of operation is obtained. The arc is easy to start and maintain and the apparatus is designed for smooth and rapid deposition of metal with the necessary penetration. This new welding generator also embodies a new feature for use in connection with the welding of light cast-iron sections.

### Air-Driven Generator for Safe Electric Lamp

Through the invention of a portable, pneumatic-electric lamp, another step forward has been made towards more effective illumination in collieries and in other places where electric sparking or an open flame might prove disastrous. A good light at the coal face or in the roadways simplifies the work of coal digging and, likewise, increases the safety of the miner by making more

**Pneumatic-Electric Lamp**

This vertical section view shows the turbine, generator and light bulb of this safety lamp.

clearly visible cracks and other signs indicative of a falling wall or roof. Efficient lighting also tends to reduce the much dreaded disease of miner's nystagmus; and, apart from added security, assures an increased output. In this connection it is interesting to note how compressed air, by improving conditions and by reducing hazards, has again come to the assistance of those who work underground.

Though this new lamp is especially fitted for service wherever explosive gases may be encountered, as in collieries, near gasoline tanks, etc., there are also many other places where it may be used to advantage. For example, where a slope or tunnel is being driven by means of compressed air it is much more convenient to employ a number of these lamps than to carry electric cables along as the work progresses. The lamp gives a bright light; and draws its operative air from the same source that supplies energy to drive the rock drills or other tools.

In designing this lamp, particular attention has been paid to the elimination of fire risks. The electric generator is an alternator with a revolving field magnet. Hence, there are no rubbing contacts or brushes of any sort which might cause sparking. The whole generator casing and the glass cover which protects the electric bulb are in communication with the exhaust side of the turbine; and a pressure of from 1 to 2 lb. per square inch is maintained by a spring-loaded exhaust valve. The outside atmosphere cannot, therefore, obtain access to the interior of the lamp when the latter is operating.

For service in coal mines, the lamp is provided with a further safe-guard—a device which cuts off the current from the bulb contacts should the excess pressure within the protecting glass cover fail through any cause. Any accumulation of gas in the protecting glass, or in the body of the lamp is prevented by a small hole communicat-

ing with the atmosphere so that a steady stream of scavenging air passes through the whole lamp whenever it is running.

The lamp body consists of two cylindrical castings. One of these carries the generator stator, cut-out, lamp holder, and protecting glass, while the other holds the bearing that supports the turbines, the turbine jet, governor, and exhaust valve.

This turbine is fitted with a single nozzle that can be easily detached for inspection or replacement. This nozzle is provided with a strainer to arrest any particles of dirt which might otherwise be drawn into the nozzle and clog it. The lamp is furnished with nozzles of six different sizes for pressures ranging from 35 to 120 lb. per square inch. With a 24-watt bulb and pressures of from 80 to 100 lb. per square inch, there are consumed approximately 4 cu.ft. of free air per minute, while 5 cu.ft. of free air per minute are needed when the lamp is operating at a pressure of 40 cu.ft. per square inch.

The complete lamp with swivel mounting weighs 14 to 15 lb. not including the air line or control valve. It has a normal rating of 24 to 36 watts—

**Turbine and Generator Rotor**

A sparkless generator with neither slip rings or commutator supplies current to the lamp which is sealed from external air. The lamp may therefore, be used in dangerous gaseous mixtures.

the equivalent of gas filled bulb of about 32 and 50 cp. respectively. Standard 12-volts, automobile head-lamp bulbs are employed; and the lamp is supplied with opal glass, to give a diffused light, or with a reflector, if a concentrated beam is desired.

These lamps are manufactured by the M-L Magneto Syndicate, Limited, Victoria Works, Coventry, England, and were recently described in *Compressed Air*.

### Transformer-Oil Filter Has Bell to Test Connections

Another improvement has been added to an oil filter press made by the General Electric Co. An air bell for testing the suction piping, so as to avoid mixing any large quantity of air with the transformer oil as it is being purified, has been applied to the press. This

air bell is arranged so it can be pumped up to the shut-off pressure of the filter-press pump. The pump is stopped after the suction-pipe valve is closed at the transformer drain, then the stored air is automatically released against the oil in the suction piping. Leaks are easily detected by oil coming through defective parts or connections. Air bells are available for existing filters.

**Filter Affords Oil of High Dielectric Strength**

This 30-gal. per minute oil-filter is equipped with an air bell to detect leaks in the suction-pipe connections. Air in these connections may be mixed with the oil, and its dielectric strength may be lowered.

## The Old, Old Question

THE DIFFICULTY and perhaps injustice of curing overdevelopment of coal by arbitrarily prohibiting the sinking of new mines is illustrated by the case of North Carolina. That state needs more power. The demand already has reached a point that justifies the development of home deposits of coal, in spite of factors which have limited their exploitation up to this year, according to the state's geological survey. The Deep River field with a present potential output of only 100,000 tons annually is especially at the fore. Should this field be encouraged to increase its output during the next few years to the million-ton mark which seems, to the state survey, to be "a reasonable vision"? Who is there to say North Carolina nay, especially if she embarks broadly and intelligently upon a program of byproduct coking? It is the old, old question which has no answer.

## Yes, It Can Be Done, Mr. Lewis

THERE really is such a thing as fearless, righteous control of a labor union. The International Pressmen's Union of North America proves it. So we respectfully invite the attention of John Lewis, "the most powerful labor leader," to the fact that President Berry of the pressmen, who whipped back into line the New York locals after a strike in violation of contract and who then made them pay the cost of that strike, has been upheld by the International at its Knoxville convention. Such a thing as punishing contract violators is, therefore, possible, and we don't want Mr. Lewis to overlook it.

No, we haven't forgotten that President Lewis booted Alexander Howat and the whole kit and caboodle of Howat office holders out of the union when they struck in Kansas in spite of Lewis' orders. That was considerable, of course, but we must add that defense of the sacredness of contract was not the only thing that motivated our dogged faced (the first adjective has two syllables, not one) miner chieftain. Howat was and is a radical whose policy is to destroy everything at all costs. He would gleefully destroy the miners' union if he could. In fact there was some slight danger of that very thing for radicalism just then was on the gain. So Mr. Lewis, in smacking Howat flat was defending the contract with one hand but with the other, and with every political force at his command, he was defending his own union organization.

The question that occurs to us is: Why hasn't the dogged (two syllables again) faced miner president risen as gallantly to the defense of the sacredness of other contracts that have been broken repeatedly? There were plenty of opportunities. But Mr. Lewis and his state chiefs have not made the rank and file understand that the whole force of the organization is behind signatures on contracts. Mr. Berry has made

New York understand this, and his rank and file support him. What ails the rank and file of miners? Are they contract violators by nature or is it just that President Lewis is afraid of them?

## Searching for the Causes

DURING recent years we have noted considerable progress being made in the more efficient and safe use of electricity in the mines. Electric drives have been applied to equipment which previously had been driven by steam engines because of fire or explosion hazards. Higher voltages have been introduced into the mines. Some companies have successfully applied electrical equipment which not long ago was considered highly dangerous.

Much of the credit for the success of this work is due to the careful and considerate engineering of some few of our leading engineers and also to the work and investigations of the Bureau of Mines. Experimental work, research, investigation and tests of the Bureau have shown the dangers of the use of certain types of apparatus when they come in contact with gaseous mixtures. Tests, recommendations and approvals markedly have reduced hazards of electrical equipment. Today we have permissible electric lamps, controllers, headlights, locomotives, fuses and portable storage battery power units; also, recommendations and suggestions which, if followed, greatly reduce liability of accident from other sources.

## Others Suffer Too

COAL MINING isn't the only industry suffering the pains of overdevelopment. Consider oil. Always reckless, always prodigal, the host which produces American oil rushed men, money and machinery around the country in the boom days during and immediately after the war, sinking 25,000 wells and half a billion dollars in twelve months! The country had to have that oil and it got it. Since then the host has been busy trying to save itself from inundation by the flood it produced. The best protection the oil host could raise apparently, was a counter flood of more oil.

The results of this policy are many and disturbing. Chief among them is waste. Where the coal producer leaves an average of only a little over one-quarter of the total deposit in the ground, the oil man leaves three-quarters. And there are oil losses in handling and consumption that rival the well-advertised wastes of coal. While, of course, strenuous efforts are made to check this heavy loss of oil, the dominating idea in the head of every oil man is: "Where can I bring in more good wells?"

"It is all too evident," says George Otis Smith, director of the U. S. Geological Survey, "that the oil business is traveling 'in high' with the gear shift locked. Everything is speeded up; the urge of ever-

increasing consumption stimulates the provision of surplus capacity in wells and refineries; then a lively competition among producers leads to an artificial stimulation of demand, and the merry round goes on. It is a pace that kills—and loses money.”

So the coal man with the weight of non-producing mines crushing him down is not the only fuel producer harassed by overdevelopment. His industry has much grief in common with the oil man's. Somehow the less spectacular coal industry seems to us the sounder of the two. Its wastes are probably less, its future is better assured because its resources are, and its financing has no \$300,000,000 a year of fraudulent stock promotion charged against it by the Postoffice Department, as had the more alluring oil.

### “Standardization” Means Something Now

ALL THIS TALK about standardization which the country has heard these last few years is not mere high-flown language. There has been much definite accomplishment, thanks largely to the energy and resources of Secretary Hoover's Department of Commerce at Washington. Already the lumber industry has reduced the number of lumber-yard items by 60 per cent, a simplification that is counted on to check to a considerable degree the waste in that industry conservatively estimated at \$250,000,000 yearly. Woven wire fencing manufacturers have reduced their styles and sizes from 552 to 69. Hollow building tile types, sizes and weights have dropped from 36 to 19; forged tool varieties are down 46 per cent and so on. The list of simplifications is a long one.

Unfortunately there is not yet any extensive reduction to report in industries directly serving coal mines, nor in coal mining practice itself, although Col. Roberts' committee of the American Mining Congress is keeping the subject alive. The campaign of education is a long, uphill fight and can't be won in a day. But it can be won. Excessive stores of repair parts in mine stockrooms is one thing that is going to help the advocates of standardization. Some mining companies have already realized the cost of capital frozen up in such stocks. Others are waking up to it. Thus perhaps the propaganda has sunk deeper than we realize.

### The Intangible Something

THERE MUST be co-operation in any organization. No one was ever heard to contradict the many and frequently repeated statements to this effect. But, there is something in a highly successful mine-operating organization which came before and made co-operation possible. We seem to have no single word by which it is adequately expressed. It is in reality an urgent desire on the part of the salaried employees to promote the general welfare of the business.

There must be a good reason for this desire. In some cases it seems to be prompted by nothing more than a sincere respect or high regard for superiors, coupled perhaps with a sense of obligation because of fair treatment accorded or favors received. In other cases, ownership of dividend-paying stock of the employing company is the secret. Again, we find rare instances where a personnel is made up almost entirely of men who are far above the average in guarding the employer's interest.

Careful analysis of successful organizations would

perhaps disclose other secrets for promoting the interest of those who are in positions to “make or break” the average coal-mining company. There must be good management, and therefore real co-operation, but before this can be secured the management must in some way furnish an incentive for the employee to entertain at all times a desire for the general good of the firm.

### Let Coal Alone; That's All

WE AGREE with President Hutchinson of the National Coal Association that the one most important thing the coal industry needs is to be let alone—just let alone. It seems such an easy boon for the country to grant, yet what is the use of expecting the country to grant it? The whole coal industry surely knows that the only way it can protect its right to mind its own business is to fight for it. Imagine having to fight for a privilege which ought to be universal! But there are worse plights. One of them is to be compelled to accept the deserts of him who will not defend his own just cause.

If there are any thinking men in the coal industry who believe that they are secure against such bitter deserts, let them take heed of the straws in the gusty wind of the present national political campaign. Government-ownership sentiment is abroad in the land. The body of propaganda to which it belongs is rolling up a vote which next month will astonish some of these coal mine owners who lunch at the club together and easily convince each other that sound conservatism is bound to prevail. They are not counting even the union coal miners, who are certainly going to poll a heavy radical vote along with other dissatisfied elements.

This is not a prophecy that the next president of the United States will be a radical. But it is a prophecy that a radical sentiment for government ownership will register heavily at the polls next month and will be persistent in the next Congress. It may not put forth an immediate demand for public ownership of coal mines. A low-price year like 1924 is a poor one in which to tell the people they can run mines better than the owners. But it is not such a bad year to talk them into running railroads and other utilities. And coal is always next after railroads. That is the point.

Mr. Hoover has some sound arguments against government ownership of such utilities. He points out that utility service is better in America than in any other country, and that the 2,700,000 employees are paid wages giving the highest standard of living and comfort on earth. He shows that our railroads under government control during the war lost \$1,600,000,000 that was paid in taxes by the people and that the roads since then have not managed to bring their average earnings even up to 4 per cent. There is already commission control over rates and issuance of stock by utilities; why should we have more control than that? If the utilities were to be bought by the government, a tax revenue of \$600,000,000 would be stopped and the country would have to make it up in added tax burden.

Many a sane labor unionist sees the truth of these things, yet it cannot be denied that the government ownership nostrum is “going good” right now. The coal industry should awake to this fact. Sitting back and viewing with alarm from club windows will accomplish little. A hot battle to be let alone is immediately ahead. The sooner the industry pitches into that fight the better its chance of being let alone.

# Proper Handling and Storage Reduce Oil Losses

Higgledy-Piggledy Oil Storage Is Wasteful—At Some Plants One Fourth of the Lubricant Purchased Is Lost—Storage Underground in Tanks with Metering Pumps Conserves Lubricants

By ALPHONSE F. BROSKY  
Assistant Editor, *Coal Age*  
Pittsburgh, Pa.

IT WOULD not be far from the truth to say that at least 25 per cent of the oil purchased by the coal industry is wasted. Although unquestionably the major portion of this loss results from too-generous an application of oils and greases to the moving parts of machines, the fundamental cause of waste lies in the methods employed in storing, issuing and otherwise handling the lubricants before they are actually applied. The primary requisite for preventing much of this known waste is adequate facility for storing lubricants. System in the management of mines today is being extended to include this important item of production cost. Ten years or more ago it was a common sight at the mines to see barrels of oil scattered about with no pretense at orderliness. Spigots were not always closed tightly; sometimes they were not used at all.

### RESULTS OF CARELESS STORAGE AT MINES

The direct result of all this carelessness, chaos and confusion was that the ground on which the barrels stood fairly seeped oil. Men were allowed to help themselves to as much lubricant as they wanted as often as they desired. And when only a gallon or two that required coaxing to pour out remained in a barrel, this container was abandoned as empty and a full barrel tapped. This word picture of carelessness and waste is true to life and may yet be seen at many mines. The accompanying illustrations show several methods used for storing oil at the mines. Each has its place though as far as possible they have been arranged

in an ascending scale of merit, Fig. 1 exhibiting the most wasteful method and Fig. 4 the one most satisfactory and economical. Enough already has been said concerning the slovenly methods depicted in Fig. 1. If a company feels that it cannot afford to erect an oil house furnished with reservoirs and pumps, it at least can provide a rack constructed of rails resting on piers as shown in Fig. 2. By so doing a noticeable improvement over conditions existing in Fig. 1 is effected.

### OIL STORED IN TANKS ACCORDING TO GRADE

A still better method of storing oil is shown in Fig. 3. Here oil is emptied from the barrels in which it is received into tanks resting upon or raised slightly above the floor of the oil house. Three grades of oil are kept in a like number of tanks. In this particular instance one grade is for engines, another for pit cars and a third for conveyors. The methods illustrated in Fig. 4 are those used at the Lewis Mine of the Hudson Coal Co., near Clarksburg, W. Va. They are recommended as facilitating not only the storage but also the handling and issuing of lubricating oils. A better arrangement would be difficult to conceive. The oil house at the Lewis mine is 15-ft. square inside and is constructed of concrete blocks. It is provided with a cellar in which three steel oil drums are installed 5 ft. below the frost line. The floor of this building is of concrete reinforced with 40-lb. rails. Each of the three tanks has a capacity of 283 gal.

FIG. 1  
Slovenly Storage

Everything should have its place at a mine, in such a location that the worker will not be unnecessarily exposed to danger in reaching it. Placing these oil barrels between a main line and a mine track renders the oiler's job unnecessarily hazardous. They were probably placed here for the sole reason that this was a convenient dumping point from the freight car.

Fig. 2—Orderly Open-Air Oil Storage

If an under-cover storage cannot be afforded this picture shows the next best alternative. Here not only has order supplanted chaos but the barrels are supported at convenient height above the ground where their spigots are readily accessible.

and holds a particular kind of oil or that intended for some specific purpose. The pumps are so arranged that they may be adjusted to measure out a given quantity of oil, and float gages indicate the quantity remaining in the tanks at all times. As little space is occupied by the pumps there is sufficient accommodation inside the house for storing barrels of oil and grease.

#### GOOD LOCATION OF OIL HOUSE SAVES LABOR

Mines producing large tonnages of coal are big consumers of oil. At such plants provision should be made for eliminating all needless labor entailed in handling barrels between the railroad car and the oil house. One excellent plan for this purpose was adopted by the Jamison Coal Co. at its No. 7 mine at Barrackville, W. Va., now owned by the Bethlehem Mines Corporation. At this particular plant the oil house was located on the same spur as, and about 60 ft. from the supply building. The floor of the structure was at an elevation slightly lower than the floor of a railroad car, so that a bridge plank could be laid between the two levels.

All in all the layout was one which greatly lightened the labor of transferring barrels from the cars to the oil house. One end of the building was occupied by tanks and pumps, somewhat similar to those shown in Fig. 3, while the remaining space was used for

Fig. 3—Inexpensive Yet Efficient Storage

A small fire-proof building and three storage tanks fitted with a pump is about all that is necessary for this kind of a storage. Its chief shortcoming lies in the fact that the oil is unprotected from cold and in winter may become decidedly sluggish. A wooden incline facilitates raising full barrels to the rack above the tanks.

the storage of barrels which were rolled onto four slightly elevated tracks constructed of ordinary mine rails.

A few recommendations for the better handling of oils as suggested by the best practices now in general use may be enumerated as follows:

(1) Oil should be kept under lock and key and issued by the man in charge of supplies only upon presentation of a properly signed requisition.

(2) As a precaution against the spread of fire, oil should not be stored in the regular supply house or in any other building which, if burned, would result

Fig. 4—Modern Oil-Handling Equipment

Means here employed for storing and issuing oil strongly resemble those used in an up-to-date gasoline filling station. The storage tanks are located in a cellar below the frost line. The pumps are provided with meters and the tanks with indicating floats so that an accurate check can be kept on the quantity drawn from the tanks and that remaining on hand.

in a heavy loss; it is wise to construct a fireproof building for storing oil. This should be placed at a distance of at least 60 to 100 ft. from any adjacent structure.

(3) The arrangement inside the oil house should insure sufficient warmth in the winter months to maintain the fluidity of a medium or heavy oil at or near the consistency attained in summer.

(4) Oil should be emptied from the barrels in which it is received into storage tanks from which it should be removed by pumping.

If these recommendations are adopted either wholly or in part, an appreciable saving will be realized. Furthermore, the potentiality of the fire hazard will be lowered. This is a consideration that cannot be disregarded as the danger of fire is ever present.

# Details of Actual Mining in Alabama Coal Beds

Thickness of Bed and Its Pitch Determine the Plan of Mining — On Moderate Inclinations Cars Are Taken to the Face — In Steep Beds Chutes or Conveyors are Used

BY MILTON H. FIES

Vice-President, De Bardeleben Coal Corporation,  
Birmingham, Ala.

JUST as a thin seam was treated in detail, as an example of a flat Alabama bed, a measure of medium thickness will be considered as being typical of the medium pitching class. Deposits of this type in Alabama are found principally in the Cahaba field. Conditions here encountered are extremely variable. All the beds pitch; in seams now being worked the dip varies from 5 to 49 deg., the roof over the coal varies from fairly good to bad; in some instances, entries and roadways in rooms are cross-collared. The rooms are timbered closely with heavy capboards over the props. The bottom varies from hard to soft. With these extremes in mind, it is manifest that the systems of mining and timbering followed differ from mine to mine, or even from section to section in the same working.

Coal beds in this field are opened on slopes that follow the coal from the outcrop (see Fig. 14). At intervals of from 200 to 300 ft., depending on the thickness of the measure, entries or lifts are turned right and left from the slope on the strike. The slopes have one or two air courses paralleling them, with a pillar 25 to 50 ft. thick between. When two air courses are driven, one is brushed, if the thickness of the coal makes it necessary, to a height of 6 ft. so that it may serve as a manway. This passage is usually 10 ft. wide. The other air course is from 6 to 13 ft. wide and is driven to the height of the coal. Air courses parallel the cross entries, generally on the dip side. The entries are driven "water level"; that is, following the undulations of the seams on slightly rising grades, to facilitate transportation and drainage. Rooms are turned off the lifts to the rise on 35- to 60-ft. centers. The coal is won, where the pitch is not too steep and the thickness of the bed permits, by delivering the car at the face with mules or by the gravity method.

## ON MODERATE PITCHES CARS ARE JIGGED TO FACE

The general practice is to use the gravity method in beds of this class, where the pitch varies from 5 to 20 deg. Rooms are driven to the rise and double tracked, the track being placed close to ribs and extended to within about 10 ft. of the room face. Pulleys, from 8 to 12 in. in diameter, are clevised to posts set about 5 ft. in advance of the room tracks. A rope of ample length to provide for room advancement and encircling the pulleys, is attached to the loaded and empty cars. An improvised braking device (see Fig. 15), situated midway between and in line with the pulleys, enables the miner to regulate the speed of the outgoing car, as it pulls the incoming empty to the face. Such a method requires great care in the laying of room tracks, in the setting of pulley timbers and in the use of the rope.

In advancing rooms three lengths of rope are used; these ropes are 150, 250, and 350 ft. long. There are two links in each rope, which are fastened to it by clamps, the surplus rope being thrown on the mine cars; these links are moved along the rope as the room advances. When the room has progressed beyond the point where one length of rope can be used, this length is moved to some other room and a longer one substituted. The ropes are  $\frac{3}{8}$  to  $\frac{1}{2}$  in. in diameter, depending on the pitch.

It has been found that patent brake pulleys are not

Fig. 14—A Mine in a Bed of Medium Pitch

A slope is driven from the outcrop directly down the pitch. From this levels are turned to either side and double-tracked, double-necked rooms turned up the pitch. Air courses are driven below the levels. Cars are jugged to and from the face.

successful. Sprags are used in the wheels of loaded cars where the pitch is 12 deg. or over. On this pitch wooden room rails are generally used as the damp steel rail does not give enough friction, even though the wheels are spragged.

A modified plan of mining a bed of medium pitch is shown in Fig. 16. The mine is developed through a slope, together with an air course and a manway. Level or strike headings driven double, spaced 700 to 800 ft. apart and averaging about 10 ft. wide, are turned right and left off the slope. Auxiliary slopes, or "dips," are turned off the headings about every 600 ft. The system of mining employed is the room-and-pillar panel plan with all wide work paralleling headings and auxiliary slopes paralleling the main slope. Hoist headings are driven to the rise a distance of 100 to 120 ft. off the headings for the purpose of handling coal from dip panels. Rooms, averaging 24 ft. wide with intervening 20-ft. pillars, are turned right and left off dip slopes and a barrier pillar approximately 40 ft. thick is maintained between the strike entry and the first room turned off dip slopes.

Coal is hauled, by rope, out of dip slopes by an elec-

NOTE—Third part of article entitled "Alabama Coal-Mining Practices," presented at the Birmingham meeting of the American Institute of Mining and Metallurgical Engineers.

Fig. 15—Gravity System or Jig in Operation

Braking is applied to the rope by the extremely simple yet efficient means here shown. The speed of the incoming and outgoing cars may thus be controlled. Sprags in the wheels are also employed if the pitch is sufficiently steep to warrant their use.

tric hoist placed directly in line with them but to the rise from the heading. From main partings in headings, coal is hauled to a side track, and thence up the main hoisting slope to the surface. Coal is undercut with machines in rooms off dips, but solid shooting is used for breaking down coal in all narrow work.

#### LONGWALL MINING PRACTICED TO SOME EXTENT

There are some modifications of this system, but they consist chiefly of semi-longwall operation. The application of this system is the same as that later described as applying to thick seams steeply pitching. Where thin and thick beds are mined on medium pitches, the method used is the same as that described for measures of medium thickness except as to the handling of rock in the thin seams and the depth of rooms in the thin and thick coals.

At one mine in the Cahaba field, a longwall system of mining has been practiced since 1906. This is employed in the Montevallo seam, a typical section of which was shown in Fig. 1, *Coal Age*, Oct. 9, page 474. (This seam is of medium thickness and medium pitch.) This particular mine, Fig. 17, was first developed through a slope on a room-and-pillar system, the rooms being cut together after they were necked and driven up the pitch. This system was continued until the slope had advanced about 2,400 ft. when the mine was changed to the longwall system. After the slope was driven through the basin, which was only 200 ft. wide, the bed began to slope upward on about a 12 deg. pitch, and the walls were advanced on the rise. Electric hoists are used to pull the cars up the pitch. One main hoist raises the empties to a common point of distribution, from which hoists located along the entries leading to the walls pull the cars to the face and drop back the loads. These hoists are equipped with 27½-hp. motors and have a rope speed of 400 ft. per minute.

The walls are 300 ft. in length and have been mined advancing. Experience has proved that if they are kept within 30 to 50 ft. of each other, when the weight comes on it is equalized between them. It has also been found that if the walls are kept 250 ft. part, the falls may be handled on each wall independently. Thus, when the wall farthest advanced gets a fall, it does not affect the coal through which the adjoining wall must be driven. The system of advancing the walls

and the location of the hoists for handling the empties are shown in Fig. 17.

When the walls are driven to the rise, a break occurs every 100 to 150 ft. unless a slip or cleavage line appears in the roof. This naturally brings on a break more quickly. Cover over this mine averages 600 ft.

Cribs are built along roadways and timbers are placed as indicated in Fig. 18. Timbers are set on 4-ft. centers staggered, with 2½ by 4-in. straps. These timbers are 1½ in. in diameter for each linear foot of length and are left in place. If the gob is inadequate, soft-wood cribs (usually of old timber or soft pine) are built behind in staggered position and left in place to serve as a cushion. The performance and condition of the roof determines whether or not the cribs must be built; where slips or cleavages occur, more cribs are required. If the roof has a tendency to fall more quickly than is normally the case, additional cribs must be built to counteract this feature.

#### DOUBLE ROWS OF CRIBBING PROTECT ROADWAYS

Headings are advanced 100 ft. under the coal in the bottom, the measure consisting of alternate coal, rash, and slate. The coal over the heading is then removed as the wall advances. The roadways are protected by cribs set in double rows. The conveyor used along these faces is of the shaker type. This is an English machine, known as the Mavor & Coulson shaker, or the reciprocal longwall conveyor. It is made in sections, each 9 ft. long, which are connected by eyelets and bolts. The motor driving the conveyor is placed be-

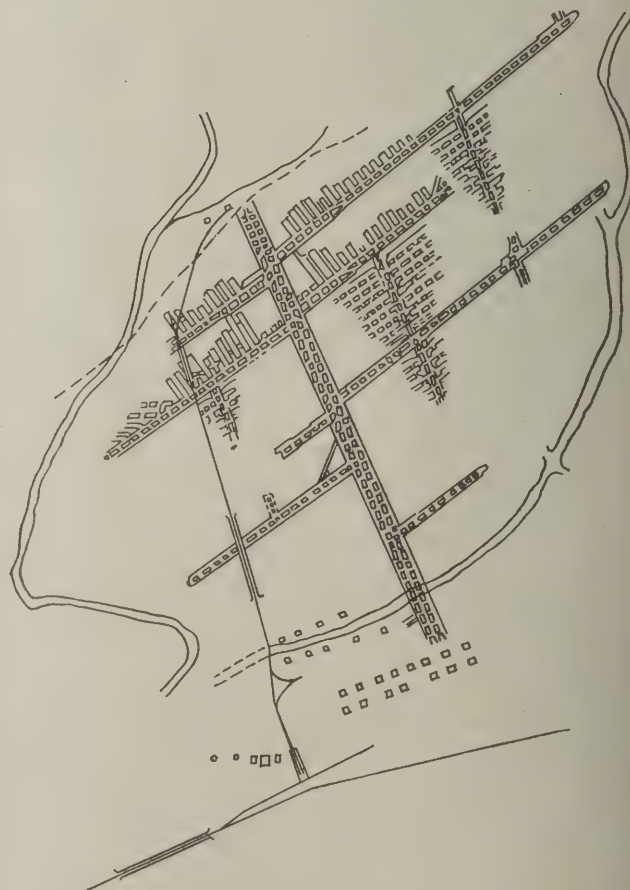

Fig. 16—Modification of Mining Used on Medium Pitches

A slope, an aircourse and a manway are driven down the pitch. Double levels are turned from the slope at intervals of from 700 to 800 ft. Room-and-pillar panel mining with all wide work paralleling the headings and auxiliary slopes paralleling the main slope, is the system followed.

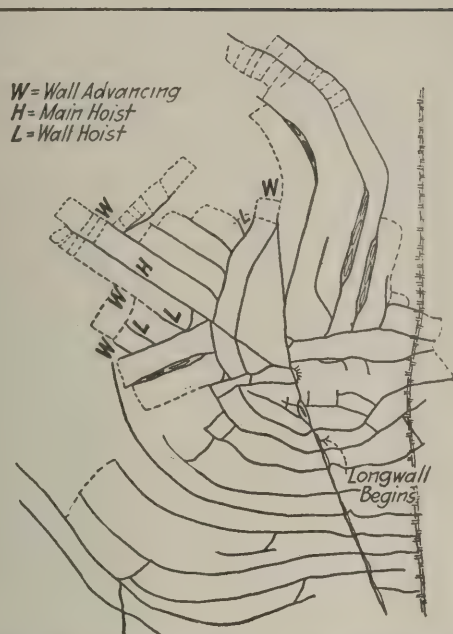

Fig. 17—Longwall Mine in the Cahaba Field

Longwall extraction has been followed in this operation for eighteen years, although the mine was at first developed on the room-and-pillar system. Electric hoists are used underground for car distribution. Operation is conducted advancing.

tween the rows of cribs and is connected to it by means of a rope.

There has been much discussion among engineers as to the proper place for connecting the driving mechanism to this type of shaker. At this mine, experiments to determine the proper location showed that it was more successful to drive the pan from the discharge end. The mining machine cuts its kerf in the rash directly over the bottom coal. Experience has demonstrated that it is most satisfactory under this system of mining to make the length of cutterbar on the machine 1 ft. for every foot of height of coal. In other words, a 4-ft. bed would require a 4-ft. cutter bar.

Coal in this mine is hard, without any butts or faces. With the system of mining described, it yields 67 per cent of lump coal over 4 in. in size, 9 per cent of  $1\frac{1}{2} \times 4$ -in. egg, and 7 per cent of  $\frac{1}{2} \times 1\frac{1}{2}$ -in. furnace nut, or a total of 83 per cent of domestic sizes.

A thick bed, known as the Henry Ellen or Mammoth,

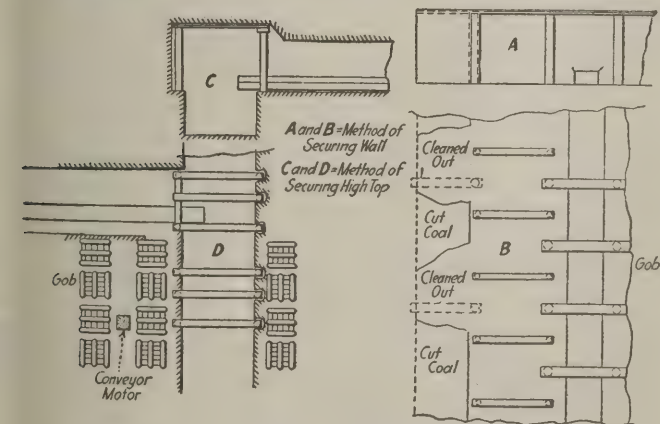

Fig. 18—Details of Longwall Timbering

Props, three-piece sets and cribs are used to support the roof. The cribs are chiefly employed however to ease the roof down. Shaking chutes are utilized to move the coal from the faces or walls to the mine cars. These are motor driven the motor being placed near the discharge end.

in the Cahaba field, is shown in Figs. 19 and 20, which illustrate the method employed in mining steeply pitching measures. This seam is 11 ft. thick with an 18-in. rash parting about the middle of the bed, and 3 to 4 in. of slate parting near the top. The pitch varies according to location along the outcrop and distance from the surface. The bed is steeper near the outcrop and flattens out somewhat as it nears the main faults, or limestone measures. The average pitch is about 26 deg. The seam is worked through a slope driven straight down the pitch with entries or headings driven at about right angles thereto. From these rooms are turned straight up the pitch, as shown. In headings and airways, the coal is loaded directly into cars. Chutes are used in the rooms and cars are loaded from them by opening the chute end gate. The cars are hauled to the sidetrack at the slope by mules and raised to the surface by electric or steam hoists.

Fig. 19—Working a Thick Steep Bed

This shows a cross-section through an airway, a heading and an advancing room. The coal is here worked in benches, the slate being gobbled in the room and retained by crib work. Chutes lined with sheet iron convey the coal from the face to the heading where a car is loaded by simply raising the chute end- or discharge-gate.

The coal is shot from the solid with permissible explosives. Cutting shots are placed in the center of the working face in the top bench of coal. Slab, or dependent shots, are placed at intervals of 3 to 4 ft. each way toward the ribs. After the top coal has been shot down and loaded out, the middle parting of rock is removed with pick and shovel after which the bottom bench is drilled and shot up with a few light charges placed near the bottom of the bed. The top bench is carried 12 to 15 ft. in advance of the bottom bench in both headings and rooms. This bed gives off a large quantity of methane at the face of the coal, hence an efficient system of ventilation is required.

Ventilation is effected by means of a motor-driven exhaust fan connected to the air shaft by a duct fitted with explosion doors over the shaft. The air intake is through the slope and manway and is conducted throughout the mine on a split system, by means of overcasts, brattices and regulators, constructed of rock, concrete or wood, according to the permanency desired.

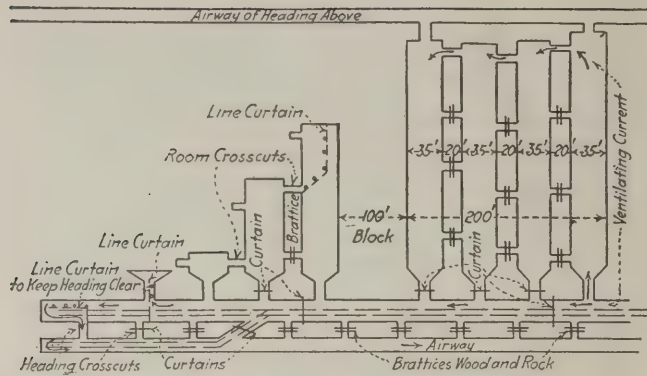

Fig. 20—Plan of Entry and Rooms in Pitching Bed

This also shows how the various working places are ventilated. As gas in fair quantity is frequently encountered it is often necessary to build line brattices or curtains in rooms or headings in order to thoroughly sweep the faces.

At times, it is necessary to use a line brattice or curtain from the last open crosscut (see Fig. 20), to the face of the working place. Electric cap lamps are used in this bed and the coal is brought down by "shot firers" after the men have left the mine. An average miner will load out from 12 to 20 tons of coal per shift.

In medium-thick beds of the third class, the difference in mining method lies in room depth and in handling rock on entries. There are no thin seams of this class mined in the state.

A semi-longwall method of mining has been applied in a few cases to thick steeply pitching beds. Fig. 21 illustrates this method. A slope was driven on the seam which pitched 35 deg. but flattened in the lower workings to about 25 deg. On the first two entries, rooms were turned up the pitch, the coal shot from the solid and loaded through chutes into 3-ton cars. This method was not a success, for the coal was almost completely shattered by the solid shooting. Accordingly, a semi-longwall system was adopted. A section of this seam is shown in Fig. 22. Entries were turned

Fig. 21—Semi-Longwall in a Steep, Thick Bed

Room-and-pillar mining was first tried but was not successful. Panel longwall faces were then opened, alternate panels being left in place, the slope and manway in all cases being protected by heavy pillars. This system is more or less of an experiment and difficulty is feared when retreat on the panels left in place is attempted.

so as to provide walls 200 ft. long. Alternate panels are left solid with the idea of advancing with one panel and retreating with the other.

The walls are undercut, beneath the bottom rock, with chain machines of the longwall type fitted with a 5½-ft. cutter bar. These machines cut up the pitch. Each cuts about 100 ft. of face in approximately 2½ to 3 hr. This is about as much as the men can "rock down" in a shift.

In addition to the regular ropes on the machine, there is a safety rope by which it is lowered on the pitch after cutting. This rope is attached to a carefully placed face jack and winds around a drum on the rear of the machine; a friction mechanism attached to this drum is operated by the machine runner. When cutting on a pitch over 25 deg. this rope is kept taut, as a precaution in case the feed rope should break. On pitches of 25 deg. or less, the undercuts in the kerf will hold the machine should the feed rope break.

As the wall advances, ordinary mine timbers about 6 in. in diameter are set about 4 or 5 ft. apart. These are left in place until they begin to show weight, when four rows of large breaking timbers 10 in. in diameter and larger, are set to within 3 or 3½ ft. of the face. Next all the smaller timbers are removed and a break follows. After the first break, it is necessary to timber for additional falls, each time the face advances from 50 to 100 ft. On the lower entry of each wall, pillars 18 ft. wide and 25 ft. long with 10-ft. crosscuts are left to protect the entry. When the wall advances beyond a crosscut, the chutes are curved into the last one left open. The coal is loaded into the chute by the miner and flows by gravity into mine cars.

FIG. 22  
Section of Coal Bed

This is a section of the coal in the mine shown in Fig. 21. It exhibits the partings characteristic of Alabama measures.

Table VII—Output per Man per Day, Tons

Thickness of Coal, inches	Average Production per Man, Tons
28-30 (machine mined)	2.16
36 (machine mined)	3.90
44 (machine mined)	4.35
84 (solid shooting)	4.65
42 (steam shovel)	8.57

This system may, with conservatism, be said to be in an experimental stage. The operator anticipates some difficulty while retreating on the alternate panels. It is planned to drive "raises" through these panels at a distance of 1,000 ft. apart. Then, if trouble develops while retreating, a wall will be advanced from a "raise" toward the face. This system is used on medium-thickness beds of medium pitch. Where the pitch is under 18 deg., the chute is replaced with a conveyor, which consists, in most cases of a chain traveling in a trough. The movement of the chain is sufficient to bring the coal to the mine car on the entry.

As an indication of the influence of the thickness of bed on the average production per man, including company men, Table VII is submitted; these figures have been compiled by a large producing company and cover several months' operation.

# Conveyor That Facilitates Concentrated Mining

Adequate Transportation Necessary to Obtain Output from Any Mine—Flexible Sectional Conveyor Makes This Possible—Ability Quickly to Lengthen or Shorten Such a Machine Is a Primary Requisite

BY N. D. LEVIN  
Columbus, Ohio

**T**RANSPORTATION within the mine is one process in coal production that causes much delay and loss to both mine owners and workmen. In many cases the men have to wait half or more of their time for cars in which to load, when they would far rather be working and making money. With the ordinary room-and-pillar system no more than one or at most two men can work in each room; consequently a great number of rooms are required in order to obtain the desired output. This means a correspondingly large investment if the mine covers an extensive territory.

The Jeffrey Manufacturing Co., of Columbus, Ohio,

The rivets take no more stress than that required to hold the chain together; the shear is taken by the lugs on the side straps. This is the strongest chain for its weight that has yet been devised.

The single chain positioned in the center of the trough is easy to get at for connecting or disconnecting. When it is desired to add a section to the conveyor the procedure is as follows: The chain is disconnected near the tail end of the conveyor, and laid out on the floor back of the conveyor, as shown in Fig. 3. The sections are held together by bolts or by pins, as shown in Fig. 4.

There is a connection on both sides at each end of

Fig. 1—Conveyor Tail Section Detached

Particular attention should be directed to the type of chain employed. Placing lugs on the side links relieves the rivet or pin from the stress of pulling the chain.

Fig. 2—Details of Chain Construction

Here the side links with their forged lugs readily can be seen as well as the grooved pins and the locking device. A hammer is used for disconnecting the chain.

Fig. 3—Inserting a Conveyor Section

When it is desired to lengthen the conveyor the first step is the disconnection of the chain. The loose end is next straightened out in line with the conveyor.

recently developed a type of conveyor that makes concentrated mining possible under many and varied conditions. One of these machines and some of its applications are described in this article. This conveyor is so constructed that it can be lengthened or shortened quickly. The standard sections are made 6 ft. long, as this is the average advance of an undercutting machine. If, for instance, the conveyor is used to take the coal away from a "shortwall loader" that makes, say, one advance per hour, the machine must be lengthened eight times in a shift.

It accordingly is evident that each extension must be accomplished quickly and easily or otherwise too much time would be lost, and the delay incurred would offset any advantage derived from the use of the machine. In designing this conveyor, therefore, aside from reliability and the lowest possible cost, the ability to attach or detach a section quickly was given first consideration.

It is evident that it will require less time to uncouple one chain than two; consequently this conveyor was made with a single strand of chain. The coupling links shown in the accompanying illustrations can be taken out or put in place in an instant.

The chain is built up of forged side straps, the same type as is employed in coal-cutting machines.

every section. The pin or bolt—whichever is used—first is pulled out; then the tail section is drawn back 6 ft. In Fig. 5 two men are shown taking hold of his tail section to move it back. It is light enough so that two men can easily carry it, or, if necessary, one man can drag it.

The lower trough or pan is put in place first, after which the upper trough is added. Fig. 6 shows a man in the act of putting the upper half of the section in position. After this is done the four pins are put in place to hold the conveyor together. Next 12 ft. of chain is added and coupled to place. All parts of the conveyor are light, so that one man can do the work if necessary, but two men can perform it easily.

The bottom of the upper trough on which the coal rides is only 3 in. above the floor of the mine, so that this conveyor is extremely low. This is of great importance when working in low coal. Another feature of the conveyor is that it readily adapts itself to rolling bottom.

Fig. 7 is a shop view of one of these conveyors with 12-in. wooden blocking placed underneath a section joint. This makes more of a sudden hump than would be encountered in a mine, yet the machine will carry coal over this obstruction.

Fig. 8 is a view of the conveyor taken from the dis-

**Fig. 4—Disconnecting Tail Section**

The tail or rear terminal section may be disconnected by withdrawing the pins or bolts that join it to the conveyor proper, thus completely freeing it.

charge end. The size of the electrical equipment shown on the left is varied to suit the length of the conveyor and the duty it will be called upon to perform. Fig. 9 is a view looking toward the discharge end, and Fig. 10 shows the tail section by itself. This is the part that ordinarily is moved back when a straight section is to be added. On the right-hand side is shown a small wheel, in the circumference of which radial holes have been drilled. These are used for slackening the chain when it is to be disconnected. A slight pull on a bar inserted in one of these holes will give sufficient slack to couple or uncouple the chain quickly.

The conveyor is reversible, this provision being necessary inasmuch as no track is laid in the entries or rooms where this machine is used, and consequently timber and other material must be handled by the conveyor.

By reference to Fig. 12 a good idea may be obtained

**Fig. 6—Inserting a Straight Section**

Top and bottom pans are moved separately, the bottom pan being put in place first. Either is light enough as to be readily handled by one man. This is a decided advantage in restricted mine passages or where speed in making a change is essential.

of the way in which this conveyor is used. A "short-wall loader" is shown at A. The sectional conveyor carries the coal from this machine and discharges it at the point B, either into cars or onto a conveyor on the lateral entry as shown. At the face C is a "conveyor loader" which discharges into another sectional conveyor at D. This latter conveyor carries the coal to the point E. The driving units for these conveyors are located at B and E respectively. Each time the face C is loaded out, the conveyor is shortened at D. The sections removed are loaded out on the conveyor to E, transferred to the conveyor serving the "shortwall loader" and are used for adding on to this conveyor at the point A.

When the shortwall loader has driven through to the next lateral entry at the point K, the conveyor is not taken out, but is left in place. The head and tail ends are removed and their positions reversed. Thus the

**FIG. 5**

#### **Moving Tail Section Back**

Lightness is an essential characteristic of any portable conveyor. The tail section of this machine is of such small weight that two men can easily carry it or one man can drag it along the mine floor. As may be seen in this illustration, hand holds are provided to facilitate moving this section. Little time is consumed in lengthening this conveyor.

FIG. 7  
Uneven Floor  
Is No  
Obstacle

Humps and hollows make little difference to this conveyor as it is sufficiently flexible to surmount them. A joint is here supported on two 6x6-in. blocks.

Fig. 10—Tail Section of Conveyor

The tail shaft is provided with an overhung disk with holes drilled radially in its circumference. This affords enough slack to permit of coupling or uncoupling the chain.

end that was nearest to the "shortwall loader" is placed at *B* and the driving or discharge end is put at the point *K*. When the face *C* has advanced to the point *E*, the conveyor is ready to receive the coal from this face and transport it to the point *K*. The same type

Fig. 8—View as Seen from Head End

The motor and driving machinery are well incased. The power of the motor may be varied to suit the work to be done or the weight of coal to be transported.

of conveyor, if desired, can be used along the face *C* instead of the "conveyor loader," the coal being loaded into it by hand. This latter method requires putting enough men along the face to load out a cut in one shift.

In mines where it is desirable to maintain the present room-and-pillar system the rooms may be driven

narrow, using a "shortwall loader" discharging to a sectional conveyor. When the rooms have been driven to their full depth slabbing cuts are made by mining machines and the coal loaded into the sectional conveyor.

In Fig. 11 is shown a room being driven 10 ft. wide with a shortwall loader, *A*. *B* is a sectional conveyor. To the right is shown a room that has been driven to its full depth. A shortwall machine is shown at *C* making a slabbing cut. *D* is the sectional conveyor that took the coal away from the shortwall loader when the narrow room was being driven and is now in position to be used for taking away coal made by the slabbing cut. *E* is a conveyor installed on the entry and em-

Fig. 11—Room Driving and Pillar Slabbing

The rooms are driven narrow and then widened out by slabbing cuts taken off the pillar ribs. Cars are loaded in trips on the heading, where unless grades are favorable each locomotive remains with its trip, successively spotting the cars until the entire trip is loaded.

FIG. 9

Looking  
Toward the  
Head End

Although the bottom plate of the coal pan is only 3 in. above the floor, making the complete conveyor low, its capacity is large, as may be judged from this view.

ployed in gathering coal from several rooms and discharging it into a trip of cars at *F*. This conveyor may be extended to the nearest entry if desired.

Many different systems of mining by mechanical means are being contemplated at the present time, and it is believed that this sectional conveyor will find a place in practically all of them. A saving will be afforded by its use because of the comparatively large quantity of coal that can be taken from a territory of given size. This will result in a lower cost of mine upkeep. No track is required where the conveyor is employed, and it is not necessary to take up bottom, shoot down top or remove rock in the entries in order to make room for cars.

Fig. 12—Concentrated Mining by Conveyors

Both heading driving and pillar withdrawal are here shown. The method is thus rapid and the output large. Cars are loaded at a single point on a heading not shown in this drawing. Unless grades are favorable the locomotive does not uncouple from the trip.

## Alberta Experiments in Making Briquets From Coal Dust Hitherto Wasted

In the fourth annual report of the Scientific and Industrial Research Council of the Province of Alberta is found a detailed account of experiments in the manufacture of briquets from the fine coal dust usually wasted in the production of coal in Alberta. This work has been carried on at the University of Alberta since December, 1922, and Prof. Edgar Stansfield, secretary of the Council, in describing it and in outlining the conclusions reached says:

"In making briquets the coal is crushed to a suitable size, if dust is not used. A batch is then weighed out, transferred to the mixer, and heated. Usually, in our test plant, 18 lb. of coal is handled in one run. The binder also is weighed out, melted and poured into the mixer, and the temperature and moisture content of the mixture regulated as required. Usually two or three minutes is found to be sufficient time to complete the mixing, but this varies with the temperature and therefore with the fluidity of the mix.

"From the mixer the batch is transferred to a fluxer, from which it is allowed to run into the feed hopper of the press. As the rear plunger is drawn back, some of the material in the hopper falls into the die box. Here it is caught, squeezed between the two plungers, and finally ejected from the die box by the rear plunger, which has a longer travel than the front one and makes only half as many strokes per minute. The briquets fall onto a moving belt, are discharged at the front, collected in a box, and tested.

### TWENTY-FIVE BRIQUETS MADE PER MINUTE

"The press makes about twenty-five briquets per minute. Their size can be controlled by a regulation of the feed, but they usually were made to weigh about 4 oz.

"The briquets are classified by inspection, by their specific gravity, by drop test, and by rattler test. Of these, the specific-gravity and the rattler test seem to be the most satisfactory. Comparison of briquets made from the same coal with the same binder show that the quality of the briquet increases with the specific gravity.

"In the drop test, six briquets are given a 10-ft. drop onto a concrete floor, and the breakage determined. In the rattler test twenty briquets are placed in a container, which is revolved 200 times at 32 r.p.m. The material rubbed off the briquets as they revolve is then weighed, and the percentage determined.

"Tests were made to determine the best sizing of

the coal, best temperature for mixing, minimum time required for mixing, best temperature for pressing, also the effect of the addition of steam to the mix, and changes of pressure in the press.

### SOFT COAL-TAR PITCH USED IN TEST WORK

"Soft coal-tar pitch was used for most of these tests for the sake of uniformity and because it is in some ways the easiest binder to use for test work. Comparative tests were made with other binders. While we are not prepared at present to tabulate full results of our experiments, certain broad conclusions may be mentioned.

"The quantity of binder required varies with the type of coal. Thus, a carbonized lignite requires from two to three times as much as a coking bituminous coal.

"The higher the temperature, the less time required for mixing.

"Although blowing steam through the mix has advantages and is generally employed in commercial work a better briquet generally can be made under laboratory conditions without steam.

"Increase of temperature at the press results in increase of density of the briquet, but a limit is placed upon the temperature by the increasing tendency to stick to the plunger and by the friability of a hot briquet as it leaves the press. The tendency to stick to the plunger can be reduced by steam.

### SIZE OF PARTICLES AFFECTS QUALITY OF BRIQUET

"Increase of pressure naturally increases the density of the product, but a large increase in pressure is required for a small increase in density.

"The effect of the size of particles in the crushed coal used on the quality of the briquet made probably is far less in a coking bituminous coal than it is with either anthracite or carbonized lignite. If the particles are too large or large particles are present in too great quantity, the briquet is coarse and friable. Finer crushing gives a smoother and more shiny briquet, but excessive dust increases the amount of binder required.

"The department does not intend to continue the manufacture of briquets this autumn," concluded Professor Stansfield, "but more attention will be paid to suitable binders for the various grades of coal. Whether our results will form a basis of a future industry for northern Alberta depends on so many factors that we can say nothing about it. We are concerned only with the scientific side of the problem and not its commercial application."

# Kentucky Chief Electricians Learn How To Cut Costs

Men of Ten Related Companies Hold Round-Table  
Session at Williamsburg Reviewing Money  
Saving Methods

BY J. H. EDWARDS  
Associate Editor, *Coal Age*,  
Huntington, W. Va.

METHODS that have already cut power costs and are expected to cut them deeper were discussed in round-table session by the chief electricians of the Southern Mining Co. and nine related mining organizations at Williamsburg, Ky., Sept. 25-27. The electrical men sat around a table, elbow to elbow with their superintendents, some foremen, a scattering of company officials and equipment salesman, and went vigorously at the heart of many a problem that worries coal mining men. This gathering in of men from various departments was a new plan.

They discussed differences in efficiency between new and old locomotives and how to get the best out of such motors. They developed the fact that the life of bearings can be doubled and the cost of lubrication halved by shifting from cheap black oil to good, high-viscosity lubricants. They learned that cutter chains oiled when hot deliver better service. They were convinced of the value of setting cutter bits with exactness. They described various new practices they have adopted, and produced the figures to show that the sort of study they are making in their round-table meetings pays. One of the companies, since the last meeting, reduced its electrical department costs 9 cents per ton. Many cuts in power cost per ton have been made.

There were represented at the meeting 12 properties with an aggregate output of 14,000 tons per day and operated by ten associated companies. F. A. Signer, electrical engineer for the entire group, presided at all sessions. The registered total attendance was eighty. The meeting was conducted informally where men smoked and speakers were not required to stand.

An especially interesting part of the program was the reading of reports including comparative figures of electrical department costs for this year and for the period since the first meeting at which each electrical man pledged himself to find ways to reduce costs.

In the electrical department costs of the Southern and associated companies are included: purchased power, supplies for electrical and mechanical equipment, trolley wire, line material, armature repairs, repair depart-

New Steel Tippie at Black Snake, Ky.

The first coal wast just recently loaded from this tippie at the Southern Mining Co.'s new operation. A flight conveyor moves the coal from the monitor dump to the tippie. The eight tippie motors are supplied with alternating current from the transformers in the foreground.

ment labor, and the like. Table I is a summary of the results obtained. Reductions up to 9 cents per ton were made. The few cases of small increases in cost were generally due to reasons beyond the control of the chief electricians. It will be noted that the table includes power costs per ton. The average cost per kw.-hr. of purchased power for this group of mines is 2½ cents.

## MANY INTERESTING PAPERS WERE PRESENTED

At intervals between informal discussions, papers were read by each chief electrician. These included the following: "Economy of Automatic Substation Installation," by G. L. Birch, Southern Mining Co., Balkan, Ky.; "System Employed in Maintenance of Storage Battery Locomotives," by Jonas Jones, Southern Mining Co., Colmar, Ky.; "System Employed in Case of Haulage Locomotives and Mining Machines," by H. A. Sparks, Harlan Coal Co., Perkins, Ky.; "Performance and Repairing of CE-10 Mining Machines," by Gail Benge, Mahan-Ellison Coal Corporation; "Tippie Equipment General Remote Control," by Bryan Harkness, Southern Mining Co., Black Snake, Ky.

Mr. Birch's paper described the layout and performance of an automatic substation put into use April 23 of this year. Up to the present he has had only four trouble calls to this equipment. Twice the automatic apparatus was merely performing its duty in refusing to go on the line because of short circuits inside the mine. The other two times failure was found due to dust on control contacts. Mr. Birch suggested eliminating this trouble by inclosing the contacts.

The important subject of lubrication as influencing electrical department costs was approached, as were many other subjects, by calling on each chief electrician for a verbal report of the service he obtains and his suggestions for improvement. At one mine a 50 per cent cut in lubrication cost was reported. This was made possible by going to the carefully supervised use of good grade, high viscosity lubricants instead of the cheaper oils and greases. It was estimated that double the bearing life is now being obtained. The necessity for applying the lubricant to a mining machine cutter chain after completing a cut rather than before starting a shift was emphasized. If applied when the chain is warm the lubricant works in along the rivets where it is needed the most.

Mr. Sale explained that three-fourths of a pint of

Table I—Per Ton Costs Are Improving

No. 11.....	.055	.057	.....	.055	.048

This table shows the results of close studies of power problems by the Southern Mining Co., and eight related companies in Kentucky. Electrical department costs including purchased power, parts and supplies, wire and line material, repair labor, etc., have been cut as much as 9 cents per ton. Power costs per ton show some reductions also.

"On Top of the Hill" at Black Snake

The two trolleys are supported by one row of heavy posts. A large bracket and a  $\frac{1}{2}$ -in. rod support the  $1\frac{1}{2}$ -in. galvanized pipe. The same posts support a telephone and low voltage a.c. line.

proper lubricant if applied properly is sufficient for the cutter chain during an entire shift. It is preferred to apply the oil in two doses, one after the first cut and the other during the middle of the shift, however, in some cases satisfaction is obtained by only one application per shift. Mr. Sale exhibited curves of amperage, first when using black oil on the cutter chain and later when using a good lubricant. In the first case the load was 135 amperes and in the second case 100 amperes. Mr. Signer also emphasized the poor lubrication by black oil, citing tests he had made where the load on a mining machine motor was reduced from 27 hp. to 21 hp. by discontinuing the use of black oil and substituting the use of a high grade lubricant.

Black oil will not adhere to the chain. If the chain is well oiled before beginning a cut there will be an increase of about 3 hp. before the cut is finished, most of this increase being due to decreased lubrication. Joe Gider described a comparative test during the past two years on two cutter chains, one being lubricated by black oil and the other by a high grade liquid grease. A recent inspection of the chains revealed that the first is nearly worn out, but the other is still in excellent condition. The use of a special gear compound rather than heavy grease was indorsed for locomotive gears.

Next in order was a discussion of arc weld bonds. The steel terminal bond applied with a mild steel  $\frac{1}{2}$ -in. diameter metallic electrode is the standard of the companies. The terminal is applied at the apex of the angle between the base and web of the rail and welded only along the top and end. The bonds are always put on the inside of the rails in which position the flanges of derailed equipment will not cut them off.

The same size and type of steel terminal is used on the cross-bonds; however, the terminal is turned upside down and its length placed at right angles to the length of the rail. It is welded along both sides to the top of the base of the rail. With the cross-bond terminal in this position a 90-deg. bend in the copper cable is avoided thus saving several inches in length of bond required and there is provided the required offset of the copper below the top of the ties thus affording protection. The breaking of a few rails at the point of bond application was reported but no one present emphasized this feature as being a serious objection.

The discussion of trolley wire installations and mine circuits in general was quite spirited. The importance of applying hangers or suspensions at intervals of not over 20 ft. and of aligning the trolley wire properly

with regard to the track was illustrated. A straight properly located wire means less strain and wear on the trolley wheels, harps and suspensions, also a great saving in time consumed by putting poles back on the wire. The waste of using several hangers screwed together one above the other at points of high roof was condemned. Mr. Birch exhibited graphic meter charts taken before and after a general repairing and reinforcing of bonding and feeders. These comparative charts indicated clearly the power saving achieved.

Following this came the subject of inspection of equipment in service. A point stressed is the necessity for effort in persuading the mining machine operators always to use a gage in setting machine cutter bits. A method of checking the care used by the machine operator is to gage a few of the dull bits he leaves at the shop. The bright marks indicate the last set screw position, this giving a point from which to measure.

In the discussion of substation maintenance the cases were cited of two fires being started by an accumulation of dust on top of the oil switches. One of the most important items of converter and motor-generator inspection brought out at the meeting is that brushes should never be allowed to get stuck in the holders.

In a discussion of locomotive and mining machine cables it was held that the braided type of cable lasts an average of ten months at these mines. The all-rubber cables are very much favored. The cost is about two and one-fourth times that of the braided but the life is three to five times as great.

Outside frame locomotives were favored by most of those present for use where clearance inside the mine permits. The outside frame type is inherently better than the type carried on an inside frame although, of course, it is more expensive when renewing tires. The difficulty of re-railing a wheel is overcome to a great extent in the latest locomotives by designs which afford 5 to 10-in. clearance between the bottom of the frame and the track.

One great advantage of the outside frame locomotive lies in its better journal bearings. Dirt and grit are excluded from at least one end of the bearing and the end thrust can be taken on a quickly renewed plate on the end of the shaft. The bearing is out where it can be lubricated and inspected easily. The added room between frames of the outside type is a valuable feature

where narrow gages would otherwise tend to cramp the equipment and limit the cab space so necessary in low coal where the motorman must get down almost level with the top of the locomotive.

The difficulty often experienced in getting full tractive effort out of new or newly re-tired locomotives was referred to by some. It requires the wear of about  $\frac{1}{8}$  in. of metal off of the properly tapered tread before full tractive effort is exerted. The Kentuckians find this wear takes place in

New Construction

The same standard bracket is used regardless of the length of arm. Pole extension above the bracket provides support for future wiring.

**Trolley Supports in Perfect Alignment**

This is one of the many photographs used at the meeting in connection with the discussion of trolley wire installation.

a few days or weeks depending on the service. It was suggested that possibly the tires should be furnished

with a flatter tread contour when first put in place.

A report was made on the performance of a 13-ton locomotive equipped with contactor control. Little or no trouble was experienced and it was agreed that the maintenance is less than with the drum control.

This meeting of chief electricians was not lacking in entertainment. One feature was a get-together dinner. Here good fellowship prevailed and serious thoughts of speakers were clothed and intermingled with wit and humor. The dinner was attended by most of the officials of the associated companies. The character of the whole gathering from start to finish was such as to make it impressive to those who attended. It is confidently expected that when the next session is held additional dollars and cents results will be reported from better electrical department methods suggested at this round table and more hearty co-operation between electrical and mining departments.

## Mining Congress Discusses Coal Situation At Sacramento Convention

**M**OST OF THE papers presented at the American Mining Congress convention held at Sacramento from Sept. 29 to Oct. 4, dealt with metal mining. However, there developed some interesting discussions on the coal situation.

Senator Oddie of Nevada, in discussing the needs of the mining industry, advocated the encouragement of seasonal buying and did not agree with the recommendation that the problems of the coal industry should be referred to the Interstate Commerce Commission for solution.

Falcon Joslin, of Seattle, explained the Alaskan situation and told of the difficulties experienced by those who had attempted to develop coal and petroleum prospects in Alaska. He said that Alaskans wanted laws that will stabilize property rights in mineral holdings and a system of government that protects capital and investments.

The needs of the coal mining industry were briefly outlined by S. Pemberton Hutchinson, president of the National Coal Association. His address in part was as follows:

### NEED OF COAL INDUSTRY IS TO BE LET ALONE

"The only need of the industry today is to be let alone to work out its own salvation. Over development, coupled with a somewhat depressed industrial situation, is usually given as the reason why there have recently been so many idle coal miners.

"Of course there is some over development for normal needs, caused by the unprecedented demands for coal during the war. This industry, as well as all other industries, cannot and should not attempt to support more men than are needed to meet the demand in normal times. Those mines that are today working the greatest percentage of full time are naturally those which can produce coal at the lowest cost. The situation in the industry is already improving and will continue to improve with a general resumption of industrial activity.

"It is often said that the stabilizing of production is the great need of the coal industry. By that is meant, I suppose, that the consumer shall buy an equal amount of coal each month. I do not believe that such

a plan is practicable. There is no power to compel the consumer to buy coal when he thinks he does not need it. Lack of storage space, uncertainty as to the future of his business, and consequently of his needs, will always be governing factors in the consumer's mind.

"Some advocate regular production and storage at the source of supply, but any one who is at all familiar with bituminous coal production knows that this is utterly impracticable for physical reasons at many mines, since they are in narrow valleys where storage space is not available. Furthermore, there is the cost of rehandling with a certain loss in volume and a greater loss through degradation as well as loss in interest on the money advanced by the producer to cover the storage period.

### STORAGE ONLY ADDS TO CONGESTION

"If the operator stores coal, with the consequent cost thereof, he must surely face the day when his stored and weather-beaten coal goes into competition with his freshly mined product. Those who advocate storage of coal at the mines in order to provide against a possible shortage during strikes or severe weather apparently forget that shortages have been largely caused by lack of transportation facilities. Storage wherever it involves reloading on railroad cars affords no relief from this difficulty, but rather slows down traffic and adds to congestion.

"Taking it by and large, over the long period of years since bituminous coal was first mined, the consumer has been able to secure an uninterrupted supply of coal at the pit mouth at a reasonable price. Private ownership and competition have effected this. Will government regulation do any better? I challenge the advocates of any form of paternalism to prove their case.

"The regulation of the bituminous coal industry can safely be left to economic forces. Attempts to stabilize production or buying can at best be only partially successful.

"There are certain hard facts as old as mankind which must be recognized. The bituminous coal industry is up against them and it must work out its own problems. That is the same thing as saying that the solution is economic, and other industries are faced with the same situation."

## Concrete-Lined Pipes Resist Acidulous Mine Water

Lining Is Spun to Place and Requires No Puddling—  
Tests Prove Impermeability and Strong  
Adhesion to Metal

By C. H. S. TUPHOLME  
London, England

**O**WING to the deleterious action of mine and other acidulous waters on metal pipes, and the incrustation and corrosion which occurs from this cause, an allowance in the size of the bore of the pipe has usually been necessary in order to secure the desired effective carrying capacity of the line. This allowance has been estimated by some engineers to be as high as 40 per cent. Various corrosion-resisting metals have been developed and used in the construction of pipes intended to carry acidulous waters. Most of these, however, have proved impracticable chiefly on account of their high cost.

The recent introduction, into Britain by the Stanton Ironworks Co., of a centrifugal method for making both iron and concrete pipes, is claimed by some disinterested parties to have provided a solution to this problem. By this method also it is possible to line a metal pipe with concrete, thus forming on its inner surface a corrosion-resistant coating.

In this process special runners are fitted to the external surface of the metal pipe that is to be lined. This pipe is then placed on the Stanton-Hume concrete machine and a concrete lining run to place on the inner surface in a manner similar to that employed in the manufacture of concrete pipes.

### CONCRETE PIPE SPUN TO SHAPE WITHIN MOLD

The machine employed in making concrete pipes consists of a cylindrical mold, cut longitudinally, the edges being rejoined by keys. At the ends of the mold, the internal diameter of which equals the external diameter of the pipe to be made, flanges are fixed. The difference between the internal diameter of these flanges and the inner diameter of the mold determines the thickness of the wall of the pipe to be made. Incidentally these flanges serve as wheels upon which the mold is rotated when placed horizontally upon the machine with the flanges bearing against friction rollers. While the mold is revolving at low speed the necessary amount of concrete is inserted, and spreads itself over the inner surface. The speed of rotation is then increased. After a few minutes the mold is brought to rest and the water, which by action of centrifugal force, has been squeezed out of the concrete, is allowed to run off. About 7 per cent of water is left behind in the body of the pipe.

The machine is again started and the pipe once more rotated for a few minutes. During this final spin the inner surface of the pipe is polished by passing a steel bar over it.

Pipes thus formed are lifted from the machines hydraulically after which they are passed successively through chambers containing a saturated atmosphere. They are next placed in the curing yard, kept well watered while in the early stages of setting, and the conditions for curing maintained as nearly as possible to ideal for several weeks.

Lining a metal pipe is performed in exactly the same manner as above described except that the pipe itself takes the place of the split mold. Either cast or wrought pipes may be lined with equal facility in this manner.

In testing the adhesion of the concrete to the metal a 27-in. cast-iron pipe with a  $\frac{1}{2}$ -in. lining was used. A hole was drilled through the iron only, just touching the outer surface of the concrete lining. This was then tapped and connected to a pump. Pressure was gradually applied until it reached 560 lb. per square inch. This pressure was maintained constant for a period of 10 min. during which time the pipe was kept under continuous observation. At the end of this interval moisture was seen coming through the concrete lining at a point opposite that at which the pressure was applied. The pressure was then increased to 1,120 lb. per square inch, when moisture appeared on parallel circumferential arcs 2 ft. long and 12 $\frac{1}{2}$  and 15 in. respectively from the point of pressure application. This concluded the test.

This trial clearly demonstrated the impermeability of the lining. The layer of dense concrete on the inside of the lining is the portion that is impervious to water at reasonable working pressures. By a "reasonable working pressure" is meant one at least 50 to 75 per cent above the working pressure that the pipe is designed to withstand.

### TEMPERATURE CHANGES HAVE LITTLE EFFECT

Atmospheric temperatures have no apparent effect on concrete-lined pipes. The coefficient of expansion of cast iron is only slightly higher than that of concrete (0.000011 as against 0.0000106), and although the conductivity of the metal is much higher than that of the concrete, the rate of change of temperature is so slow that no separation of the metal and concrete can take place. To demonstrate this fact the following experiment was performed:

Four concrete-lined iron pipes were successively subjected to temperatures of 80, 90, 100 and 200 deg. F., with no separation between metal and lining occurring. In order to make this test as severe as possible the pipes were rolled direct from the heating chamber into the cold air and vice versa. The pipes were left for 7 hr. at each of the higher temperatures and intermittently for 5 hr. at atmospheric temperatures ranging from 48 to 62 deg. F. In order to ascertain if any separation between lining and metal had taken place in the body of the pipe, sections were cut off from time to time and inspected.

In a freezing test a 12-in. ring cut from a 27-in. cast-iron pipe lined with  $\frac{1}{2}$  in. of concrete was sent to a refrigeration plant and left in a freezing chamber at 1 deg. F. for 24 hr. This also had no effect on the lining.

In another test two concrete-lined iron pipes were joined and caked, after which the following loads were applied:

Load, tons	Deflection, inches
0.5 .....	0.011
1.0 .....	0.019
1.25 .....	0.025
1.50 .....	0.030
1.75 .....	0.040
2.00 .....	0.101
2.25 .....	0.161
2.50 .....	0.214
2.75 .....	0.272
3.00 .....	0.315
6.5 .....	1 $\frac{1}{2}$ approx.

The sections joined were finally deflected 17 deg. from a straight line yet no sign of damage appeared in the concrete lining.

It is possible to cut a concrete-lined metal pipe with a diamond chisel. Such pipes also may be drilled and tapped in the ordinary way. Aside from the protection it affords, the concrete lining imparts a material increase in the pipes resistance to external pressures. Deflection tests have shown that the concrete lining does not add to the pipes rigidity. A 4-in. pipe placed on supports 10 ft. apart gives exactly the same deflection lined as unlined. The interesting feature of this test, however, is the fact that the concrete bends with the iron without cracking. If the pipe is fractured the break in the concrete lining follows the lines of break in the metal and shows no splintering. Even the pieces flying off when lined pipe is shattered still retain the concrete lining.

THE EXECUTIVE COMMITTEE of the National Safety Council elected at the meeting at Louisville, Oct. 2, to serve until annual meeting of members, 1925, included the following fourteen members at large: C. B. Auel, Westinghouse Electric and Manufacturing Co.; Charles B. Scott, Bureau of Safety, Chicago; Walter G. King, American Optical Co., New York City; George T. Fonda, Fonda-Tolsted, Inc.; C. E. Pettibone, American Mutual Liability Insurance Co.; L. R. Palmer, Equitable Life Assurance Society; H. A. Reninger, Lehigh Portland Cement Co.; Homer E. Niesz, Commonwealth Edison Co., Chicago; Harry E. Webber, Illinois Bell Telephone Co., Chicago; A. L. Watson, Hooker Electro-Chemical Co.; E. W. Beck, United States Rubber Co., New York City; Harry A. Adams, Union Pacific Railroad Co., Omaha, Neb.; James P. Barnes, Louisville Street Railway Co.; Dr. Otto P. Geier, Cincinnati Milling Machine Co., Cincinnati.

Double Tipple No. 32 of the Red Jacket Consolidated Coal & Coke Co., Red Jacket, W. Va.

Where coal beds lie flat and occur close together, as in the case here shown, it is often advantageous to place two dump houses tributary to one conveyor leading to the tipple. By this means the first cost of the entire installation is kept to a minimum.

## News Of the Industry

### Consumers' Reserves of Soft Coal Shrink To 47,000,000 Tons on Sept. 1

Decrease of 15,000,000 Tons Since Jan. 1—Present Supply Would Last 45 Days at Current Rate of Consumption—Retailers' Stocks of Anthracite Sufficient for 58 Days

Commercial stocks of soft coal on Sept. 1, 1924, according to the government's inventory of coal stocks, taken recently, totaled 47,000,000 net tons, a decrease of 4,000,000 tons from stocks on June 1, and 15,000,000 tons from the record of Jan. 1, 1924. The course of stocks has been constantly downward since the early weeks of the year; stocks on Sept. 1, 1924, were 9,000,000 less than on the same date a year ago, and were more than double those on Sept. 1, 1922, at the close of the miners' five months' strike; compared with Aug. 1, 1921, there was an increase of 6,000,000 tons.

Measured in terms of tons, stocks decreased 24 per cent during the first 8 months of 1924. Measured in terms of days' supply the decrease was but little over 2 per cent. These percentages are based on averages which assume that the supply was evenly distributed.

In addition to the estimated quantity in storage piles of actual consumers, the following quantities are known to have been in transit on Sept. 1: On the commercial docks of Lakes Superior and Michigan, 6,600,000 tons; in storage at the mines or at intermediate points, at least 300,000 tons.

**Anthracite.**—Retail dealers' stocks of anthracite were 71 per cent larger on Sept. 1, 1924, than they were on the corresponding date of 1923, and they were but 7 per cent less than on Nov. 1, 1921, two months later in the season. As a result of the steady movement of anthracite up the Lakes the stocks, which stood at 450,000 tons on June 1, had increased to 1,400,000 tons by September 1.

The estimate of soft coal in the hands

of commercial consumers on Sept. 1—about 47,000,000 tons—which is based on reports from a selected list of about 5,000 consumers, does not take into account the coal in the bins of householders, concerning which no data are available, nor steamship fuel, nor the tonnage on the Lake docks, which is considered coal in transit.

It will be seen from Fig. 1 that the period of accumulation of reserves that began with the termination of the miners' strike of 1922 and that resulted in stocks of 62,000,000 tons on Jan. 1, 1924, came to an end during the early months of this year. By June 1 stocks had dropped to 51,000,000 tons, and a further decline during the following three months carried them down to 47,000,000 tons.

The reports from consumers, supplemented by information from other sources, indicate that the total consumption of soft coal during the first eight months of 1924, including coal that entered into the foreign trade, was approximately 310,000,000 tons, or at a daily rate of about 1,270,000 tons. For the five months ended May 31, the average daily rate of consumption appears to have been about 1,370,000 tons, and for the three months ended Aug. 31, it was but slightly over 1,100,000 tons.

#### Stocks in Days' Supply

Fig. 2 compares the days' supply held by the seven principal classes of consumers on Sept. 1, 1924, with that on the same date the year before. Here again the importance of the rate of consumption in determining the adequacy of reserve stocks is strikingly illustrated. As against a 46 days'

supply on Jan. 1, 1924, at the rate of consumption then prevailing, the average consumer on June 1 had a supply sufficient to last 49 days, despite a decrease of 11,000,000 tons in the actual quantity on hand. On Sept. 1, after a further reduction of 4,000,000 tons, the storage piles still held a 45 days' supply at the rate of consumption in June, July and August.

In studying these figures of average days' supply, it should be borne in mind that the reserves on Sept. 1 were based on the summer rate of consumption, whereas the weeks following Sept. 1 almost invariably witness an increase in consumption owing to the change of seasons.

In Fig. 3 the variations in stocks in the several states are graphically presented. The map shows the days' supply held at general industrial plants, excluding byproduct coke and steel works. This is the largest single group of consumers, both numerically and from the viewpoint of consumption, and the one that illustrates best the geographical distribution of reserves. This group is a sensitive business barometer, and changes in its activity are quickly reflected in the coal market, and likewise important changes in the production and prices of coal are soon manifested in the stocks held by the industrials.

Over the country as a whole the industrials had a 48 days' supply on Sept. 1, against a 53 days' supply on June 1 and a 56 days' supply on Sept. 1, 1923. In the case of the industrials, also, the days' supply appears large because of the reduced rate of consumption.

As usual, the reserves varied with the distance from the mine and the character of the coal used. Consequently the map shows that New England, Wisconsin, the Upper Peninsular of Michigan, and the northern Rocky Mountain region had a 90 days' supply, and that New York, New Jersey and the Carolinas had better than a 60-days supply.

In the belt of states extending from Maryland to California, and from Texas

Days' Supply of Bituminous Coal in Hands of Various Classes of Consumers, Nov. 11, 1918, to Sept. 1, 1924 (a)

(Figures represent number of days supply would last at current rate of consumption at time of stocktaking)

	Nov. 11, 1918	Jan. 1, 1919	Jan. 1, 1921	Nov. 1, 1921	Jan. 1, 1922	Mar. 1, 1922	Jan. 1, 1923	Sept. 1, 1923	Oct. 1, 1923	Jan. 1, 1924	June 1, (b) 1924 (b)	Sept. 1, (b) 1924 (b)
Byproduct coke plants.....	35	32	29	38	42	39	19	30	33	35	34	30
Steel plants.....	45	42	42	46	48	48	27	33	39	43	56	42

Total bituminous.....	45	42	39	43	41	41	26(c)	46(c)	45(c)	46(c)	49(c)	45(c)

(a) The figures in this table are estimates based on incomplete data. (b) The rate of consumption used in calculating the days' supply on June 1, and Sept. 1, 1924, was the quantity consumed from June 1 to Aug. 31. (c) Subject to revision.

Fig. 1—Total Commercial Stocks of Bituminous Coal, Oct. 1, 1916, to Sept. 1, 1924

Figures represent millions of net tons and include coal in the hands of railroads, industrial consumers, public utilities and retail dealers. Coal for steamship fuel, on Lake docks, in transit and in the bins of householders is not included. These exceptions are important, as the coal on wheels at times has proved a greatly disturbing factor in the calculations of would-be statisticians. Figures for 1923 and 1924 are subject to revision.

to Washington none had as much as a 60-day supply, and in many stocks would have lasted less than 30 days. Some of those states, however, use mostly lignite, and in others little coal is burned owing to the availability of water power, electricity and fuel oil.

As usual, the public utilities were in a particularly strong position regarding stocks; on Sept. 1 electric power plants had a supply sufficient to last 58 days, and manufactured-gas plants had a 90-day reserve.

Complete returns from the manufacturers of byproduct coke and iron and steel showed the following reserves on Sept. 1, 1924, and Sept. 1, 1923:

Byproduct Coke Plants	
Sept. 1, 1924	Sept. 1, 1923
Low volatile.....	33 days
High volatile.....	29 days
	30 days
	30 days
Steel Works	
Sept. 1, 1924	Sept. 1, 1923
Steam coal.....	36 days
Gas coal.....	56 days
	42 days
	33 days

The greatly decreased activity at steel plants was reflected by a decrease of 39 per cent in the daily rate of consumption of coal from June 1 to Aug.

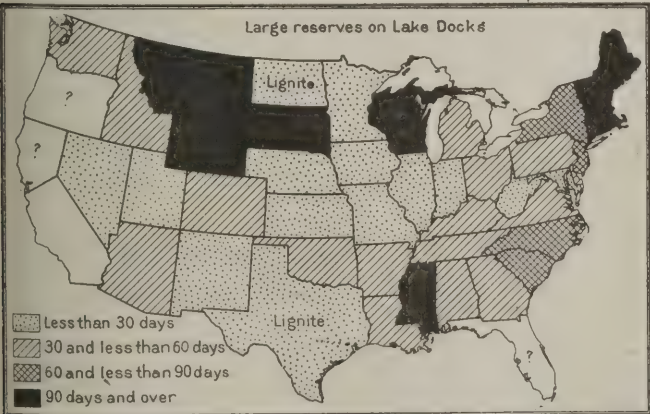

Fig. 3—Days' Supply of Soft Coal on Hand at Industrial Plants, Sept. 1, 1924

At the average rate of consumption during the summer of 1924, stocks at industrial plants, other than steel and byproduct coke, would have lasted on the average 48 days. New England, Wisconsin and the Upper Peninsula of Michigan had supplies sufficient for at least 90 days, and of the states east of the Mississippi only Illinois, Indiana, Maryland and West Virginia had less than 30 days' supply. Based on reports from 2,093 industrial plants.

Fig. 2—Days' Supply Held By Different Classes of Consumers, Sept. 1, 1924, and Sept. 1, 1923

At the rate soft coal was burned from June 1 to Aug. 31, 1924, the total stocks on Sept. 1 were sufficient to last 45 days on the average, against a 46 days' supply on Sept. 1, 1923, at the rate of consumption then prevailing. The tonnage now in reserve, although 16 per cent less than a year ago, is nearly as adequate for the present needs as was that on hand a year ago.

the supply a year ago. Compared with Nov. 1, 1921, two months later in the season, the day's supply was identical, but the actual tonnage on hand was 20 per cent less.

The total quantity of soft coal in transit has never been measured accurately, but there is sufficient evidence to indicate that the figure runs into millions of tons, and that it is subject to sudden and wide fluctuation. The available information indicates that the quantity in transit on Sept. 1 was about the same as on Jan. 1, 1924. Reports from an incomplete list of producers who store showed a total on Sept. 1, 1924, of about 300,000 tons against 385,000 tons on Jan. 1, and 440,000 tons on Sept. 1, 1923. The total quantity of unbilled coal standing in cars at the mines was about 750,000 tons.

Manufacturers of byproduct coke accumulated stocks of unsold coke during the first eight months of 1924, and on Sept. 1 a group of 21 plants had on hand a record total of 1,114,000 tons. This was an increase of nearly 45 per cent over the stocks on Jan. 1, 1924, and exceeded the previous high mark established on March 1, 1922, by more than 10 per cent.

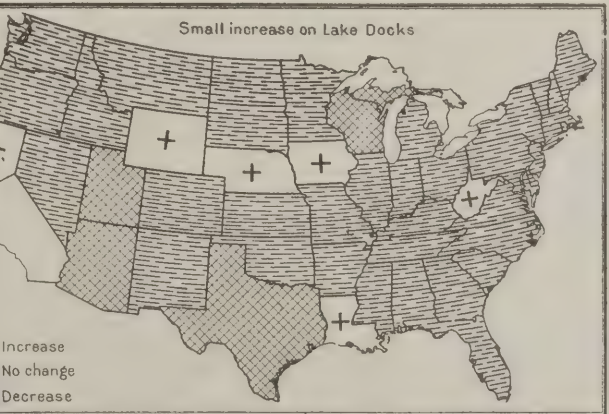

Fig. 4—How Stocks at Industrial Plants on Sept. 1, 1924, Compared With Those on Sept. 1, 1923.

The map shows, state by state, the changes in stocks at 1,839 identical industrial plants, other than steel and byproduct coke works. In only 6 states were stocks larger than they were a year ago, and in the eastern part of the country, West Virginia or W. Va., showed an increase. The decrease in stocks appears to have been due to a sharp decline in requirements, which led consumers to reduce their reserves.

## Unfavorable Reaction Develops Toward Proposed Coal Institute

Wadleigh Plan Would Include Associations of Producers, Wholesalers and Retailers—To Interpret Coal to Public and Foster Research—Stronger Local Organizations Chief Need

By PAUL WOOTON  
Washington Correspondent of *Coal Age*

Coal specialists in Washington do not react favorably to the coal institute which F. R. Wadleigh, former Federal Fuel Distributor, is advocating. None doubts Mr. Wadleigh's sincerity and unselfishness. The very fact that he has sponsored the idea has given big impetus to a proposal which would have been cast aside without serious attention had it come from anyone not known to be thoroughly public spirited.

The coal institute, as proposed by Mr. Wadleigh, is a sort of three-party affair to be composed of the associations representing the producers, the wholesalers and the retailers of coal. It is to be a center of information. Coal is to be interpreted to the public. The organization is so set forth in a dignified way the importance of coal in the national economy. It is to constitute a united front for a campaign to improve public relations. It is to foster research. It is to give technical advice in the art of using coal to the best advantage. It is to eliminate waste in distribution, and is to be a great center of statistical activity covering all branches of the industry.

### Aims to Eliminate Waste

No one attempts to dispute the fact that the aims of Mr. Wadleigh's conception are entirely praiseworthy. At a time when the industry is suffering as never before from overproduction and the attending evils of bankruptcy and unemployment, when distribution is conducted on such slender profits as to imperil its efficiency, any proposal is welcome which will eliminate waste, improve practice and unify the industry. Even the late lamented Coal Commission would have applauded the carrying out of the aims set forth for the proposed organization. It coincides exactly with the plan of constructive trade association activities prescribed by Secretary Hoover.

Desirable as is an *entente cordiale* between the various branches of the coal industry, the majority view in Washington is that the building must be done from the bottom up rather than from the top down. Before a great superstructure can be supported by the National Coal Association, the American Wholesale Coal Association and the National Association of Retail Coal Merchants, the pillars must be strengthened.

In this matter, as in all national questions affecting coal, the views of the Washington coal specialists are entitled to consideration because they reflect not only the thought in the three branches of the bituminous industry but also the viewpoint of the public and of various types of consumers.

Convincing reasons are advanced to show that the first requisites of the coal institute plan are strong national

associations functioning vigorously in their own fields. It can be said truthfully that the National Coal Association, the American Wholesale Association and the National Association of Retail Coal Merchants do not receive the support that they have the right to expect. Incidentally this situation reflects adversely on various elements within those branches of the industry.

The opinion is that the first task is to create three strong national bodies. For instance, in the matter of statistics the institute would get its figures from the national associations. These associations can furnish the facts and figures only if they in turn have the hearty co-operation of all local associations. Not only must there be hearty co-operation but there must be strong local associations before stability can be obtained by the national associations.

In studying the problems which confront our industry there is an increasing tendency to find out if there is anything in the practice of other coal mining countries which can serve as a guide to us. In this particular instance it is worth while to consider what has been done in this line in Great Britain. The association idea has advanced much further in that country than is the case here, yet there has been no federation of the associations. It is true that the British associations have carried on some of the activities suggested for the coal institute but they do not try to do things in common, although each is more ready to take up cudgels for other branches of the industry when it is under a pact, in Parliament or without, than is the case in this country.

The Lancashire and Cheshire associations for a long time have supported research on problems such as spontaneous combustion, mine explosions and permissible explosives. Other associations have been active in financing research work which the trade in this country has been willing to leave to the government. The British associations have carried statistical work to a degree not common in this country. Complete current data are available on costs, on the export trade, on employment, on wages and earnings, on the productivity of labor and on many other matters. The Mining Association of Great Britain has far more data of this character than has its counterpart in this country, the National Coal Association. It has monthly returns of cost from every field and a great mass of other data which enables that association to be the mouthpiece of the coal operator in fact as well as in name. Its board of directors is representative of all the districts. It maintains cordial relationships with other associations, but no super-organization has been created.

### Howat Ineligible for Office, Says Lewis

A recent message from President Lewis to officials of District 14, United Mine Workers (Kansas), declaring Alex Howat, deposed president of the district, ineligible for office in the organization, followed the action of several locals in placing Howat in nomination for the office he once held. Lewis explained that while the application of Howat for reinstatement was accepted by one of the locals several months ago, it has not yet been approved by the International Board, and until such action Alex is not qualified to hold office.

### Interesting Meet Planned by Coal Mining Institute

Deep interest is being manifested in the coming meeting of the Coal Mining Institute of America, at Pittsburgh, Pa., Dec. 3-5. Though all the details of the program have not been completed mining men far and wide urge that plans be made early to attend. The importance of this year's gathering to executives and operating men is only partly disclosed by an announcement of some of the subjects and speakers.

Men of national reputation will describe some of the advances during the last few years in operating methods. For instance, Thomas W. Dawson, chief engineer of the H. C. Frick Coke Co., will present a paper on "Underground Belt Transportation" and Graham Bright will read one on "Recent Developments in Electricity in Coal Mines." Edward Steidle, of the Carnegie Institute of Technology, will speak on "Modern Rock-Dusting Practices." The effect of certain practices such as rock dusting on the health of the miner will be treated in the language of the layman by Dr. R. R. Sayer, U. S. Bureau of Mines, in a paper entitled "Health Hazards in Coal Mining." Other subjects of no less importance will be presented.

Each year the institute invites men from all sections to present practical operating problems for solution, and the practice has been followed this year. At an early date the discussion leaders will meet and choose the best of these problems for "the Question Box."

### Gaskill Reappointed to Trade Commission

Nelson B. Gaskill, of New Jersey, was reappointed a member of the Federal Trade Commission by President Coolidge last week. His term had expired but it was decided at a conference at the White House between the President and Senator Edge of New Jersey to give him a recess appointment. It has not been decided, according to Senator Edge, whether the reappointment of Mr. Gaskill will be made permanent when Congress convenes.

Frederick R. Low Honored at Rensselaer Centenary

Rensselaer Polytechnic Institute, at Troy, N. Y., on Oct. 2-3, celebrated the 100th anniversary of its founding in two days of fairly continuous ceremonies which were participated in by eminent educators, delegates from practically every engineering society in this country, and a number of the leading societies abroad, and by a large body of the engineering alumni of the Institute. In addition to the unveiling of several commemorative tablets at different parts of the campus and an excellent pageant in the evening outlining the history of the school, the exercises consisted mainly in addresses by prominent educators and engineers.

The principal addresses were made by Secretary of Commerce Hoover, Sir Charles L. Morgan, president of the Institution of Civil Engineers of Great Britain; Henry Abraham, past president of the Society of Electrical Engineers of France; Luigi Luiggi, president of the Society of Civil Engineers of Italy; Arthur Surveyor, president of the Engineering Institute of Canada; C. E. Grunsky, president of the American Society of Civil Engineers; Fred R. Low, president, American Society of Mechanical Engineers; William Kelly, president, American Institute of Mining and Metallurgical Engineers; Farley Osgood, president of the American Institute of Electrical Engineers; Prof. Albert A. Michelson, president of the National Academy of Sciences; and Presidents Angell of Yale, Birge of Wisconsin, and Stratton of the Massachusetts Institute of Technology.

At a banquet, at which about a thousand were present, addresses were made by President Livingston Farrand, of Cornell; H. W. Jervey, dean of the Law School of Columbia University, and J. H. Odell, of Wilmington, Del. Honorary degrees of Doctor of Engineering were conferred on the heads of the engineering societies who spoke, and of Doctor of Philosophy upon the presidents of the universities and Dr. Michelson.

Frederick Rollins Low, president of the American Society of Mechanical

©Underwood & Underwood

F. R. Low

Engineers, who was one of the recipients of an honorary degree, has been the editor of *Power* since 1888. He was born in Chelsea, Mass., April 3, 1860, and received his education in public schools. For a while he was a clerk with the Western Union Telegraph Co., was a court stenographer from 1874 to 1880 and then was on the staff of the *Boston Journal of Commerce* from 1880-1888. This was at a time when the steam-engine indicator was coming into use, and, being interested in this new device, he did some indicating of engines. Later he invented a compound indicator and planimeter and finally started a department of steam engineering in the paper. At about this time he also invented an arc indicator, a cleaner for vertical tubular boilers, a shaft leveling target, an elevator control and a rotary engine which were developed by the Clark & Low Machine Co.

Mr. Low is the author of "The Power Catechism," "The Compound Engine," "Condensers," and "The Steam Engine Indicator." He was a councilman in Passaic, N. J., from 1901 to 1903, president of the Council in 1905 and 1906 and Mayor of Passaic, 1908 and 1909.

Western Canadian Miners Accept Wage Cut

An agreement to settle the coal strike in District 18, United Mine Workers (Alberta, Can.) has been reached between miners' representatives and the coal operators. By the terms of the settlement the miners will accept a reduction of \$1.17 a day on contract work and one-eighth reduction for day workers, which will amount to about 90c. a day for day workers. This is to be a three-year contract subject to six months' notice of cancellation by either side after March 31 next. Miners generally will vote on the proposed settlement immediately.

Negotiations on a new wage scale between the Western Fuel Corporation, of Canada, which operates mines in the Nanaimo field, Vancouver Island, and its 1,400 employees for a while proved abortive. The old wage contract ended on Sept. 30, and the company posted notices at the pitheads giving terms on which it is prepared to enter into a new wage contract.

The company took the position that there should be a readjustment on the basis of a reduction of 25c. a day. During the war what was known as a "war bonus" of \$1 a day was added to the base rate, which brought it up to \$5. The company felt that, the war being over and the cost of living considerably reduced, this \$1 should be reduced 25c. a day. The men maintained that conditions had altered so little that no reduction was warranted. There were other differences relative to the wages of contract miners on timbering and on production, but the one cited affected all workers below and above ground and was the main issue.

Ultimately a compromise was agreed to, the men undertaking to accept a 10c. a day reduction on the war bonus, making the latter 90c. and putting the base rate in effect for the next three years at \$4.90 a day. While some of the men were reluctant to adopt the recommendation of their committee the latter's advice was finally approved without dissension and a three-year agreement was signed.

## N. C. A. Directors Start Movement to Increase Use of Bituminous Coal

Despite the long period of depression through which the coal industry has been passing, the board of directors of the National Coal Association, at its meeting in Washington, Oct. 10, voted unanimously to continue the assessment of one mill a ton for the support of national association work. It emphasized a full determination to maintain an active and virile association.

Full sympathy was expressed by the board with the purposes of the proposed coal institute, but in a resolution offered by J. T. Bradley, the board registered its conviction that these purposes could be achieved more effectively and more economically by the existing organizations without the creation of a new one.

S. Pemberton Hutchinson, president of the association, reviewed the arguments presented for and against a Department of Mines, at the Sacramento meeting of the American Mining Congress, which he had attended. The board then voted its formal disapproval of the proposed department.

The board approved the action of the research committee in urging that immediate contacts be established with architects and builders looking to the construction of houses in such a way as to make most convenient their heating with bituminous coal. Steps also were taken looking to co-operation with other associations and with the manufacturers of coal-burning equipment for the opening of exhibits at which proper methods of fuel utilization might be explained to the public.

The board of directors and the research committee are much impressed with the possibilities of "keeping cool with coal," as was suggested editorially in a recent issue of *Coal Age*. Orders were issued to leave no stone unturned to ascertain the feasibility of such a development and to encourage research to that end.

Consideration is to be given co-operation with the Stoker Manufacturers Association with the idea of disseminating information as to how bituminous coal can be used with greater satisfaction.

Announcement was made at the meeting of the promotion of Thomas F. Edmunds to be editor of *Coal Review* and of the employment of C. V. Huntress as associate editor, who also will devote a considerable portion of his time to general publicity work.

Mr. Gandy reviewed the Canadian situation before the foreign trade committee. He admitted that the efforts being made by the Canadian Government to stimulate the use of Nova Scotian and British coals are causing some concern, but that everything possible is being done to safeguard the interests of American producers. The board of directors instructed the secretary to acquaint members of the association as far in advance as possible with forthcoming exhibitions in other countries where displays of American coal might be made to advantage.

## French Chemists Test Gasoline Substitute

The search of French chemists for a substitute for gasoline apparently is nearing success, two methods having been described at a conference of scientists on synthetic carburants held in Paris early this month. The first test was made with a fixed motor. Then the empty tank of an automobile was filled with the new substitute by one of the spectators. In both cases as good results were obtained as with ordinary gasoline. For its composition this new carburant needs only lignite coke and water, though charcoal dust has been used with equal success.

The second substitute was described by Professor Maihle, of Toulouse. During a study of ether salts he discovered the existence of an excess of hydrocarbon, which led him to pursue his examination and in his own words "discover a gasoline absolutely analogous to that of Pennsylvania." The new product's calorific power—between 10,800 and 10,960 calories—equals the force of the natural product, he says. His raw materials are animal and vegetable fats heated with chloride of magnesium or sodium, and only a simple apparatus is necessary.

The problem of commercial manufacture he admits, however, presents difficulties, for to produce \$85 worth of the synthetic oil it cost him more than \$150.

## Boston Shippers May Drop Pool Classification

One of the big developments in the tidewater bituminous market at Boston the past week was the suggestion by a committee of the New England Wholesale Association appointed for the purpose of devising some means of bringing about greater uniformity in offerings, that the offering by pool classifications be discontinued. This committee discussed the problem from all angles and came to the conclusion that both sellers and buyers would be best served if West Virginia coal were offered under a trade name and the analysis.

The committee submitted its plan to the board of directors of the association, and while that body has reserved opinion it is generally believed that the plan will be recommended to the members and its use urged.

## Maynard Case Postponed

The Court of Appeals of the District of Columbia has granted an indefinite postponement of argument in the Maynard Coal Co. case pending the action of the U. S. Supreme Court in the Claire Furnace case. The same principle is involved in the two cases. Each action grew out of the effort of the Federal Trade Commission to exact full information as to costs of production.

## Five Glen Alden Collieries Tied Up by Outlaw Strike

(Special to Coal Age)

Scranton, Pa., Oct. 14.—Five Glen Alden collieries were closed down and as many more worked with reduced forces on Monday as the result of an outlaw strike called by members of the general grievance committee at a meeting in Wilkes-Barre a few days before. Today showed an improvement in the strike condition with every colliery in the Lackawanna County group operating with practically full forces. The unauthorized strike went into effect despite a warning against such action by John L. Lewis, international president of the miners' union, who was informed of the general grievance committee's move. Mr. Lewis telegraphed to Rinaldo Cappellini, president of District 1, United Mine Workers, and ordered him to do all in his power to counteract the strike move.

The organizers and other district officials with President Cappellini succeeded in bringing several local unions to meetings and in rescinding the strike vote. The attitude of several of the locals who were led into the strike by the radical element and were outvoted on the motion was expressed in a resolution adopted by the Truesdale Colliery Local against obeying the strike order "first, because it is unlawful and only tends to disrupt the union; second, because the so-called general grievance committee has no legal standing in the constitution of the United Mine Workers, and third, because the only committee which is expected to be recognized by the operators is the colliery grievance committee."

## Two Fires at Anthracite Mine Within Few Days

A section of the No. 1 Ebervale slope of the Jeddo-Highland Coal Co., near Hazleton, was idle last week on account of a fire which broke out in the big vein. The fire is thought to have originated from a broken feed cable. A slight cave, caused by the high water, handicapped the working forces in reaching the flames. The obstacle was finally surmounted and the fire extinguished.

Several days later coal was found burning in the western section of the mine. Since then a large force of men has been fighting the flames.

## Zeigler No. 1 Mine Again Breaks Output Record

Zeigler Mine No. 1 of the Bell & Zoller Coal Co., at Zeigler, Ill., has again beaten the world's record of 1922. In September, a short month, Zeigler Mine No. 1 hoisted to the surface 171,907 tons.

This is the fourth record credited to the Zeigler mines. In 1917 these mines established the world's record. In March, 1922, Mine No. 1 alone established a record of 164,085 tons hoisted to the surface. In January, 1924, a record was established for the combined production of the two Zeigler mines with a total of 310,053 tons shipped during the month.

# Practical Pointers For Electrical And Mechanical Men

## Insulating Rubber Cable Ends to Reduce Leakage to a Minimum

THERE are few points on an electrical system so vulnerable to dampness, and where leakage in consequence is so common as the ends of cables where the conductors are exposed. While rubber insulated cables are among the most robust that may be used about the mines, yet inattention to details, especially where cables are used in damp places may give rise to serious current leaks. The ideal method of insulating cable ends where they are connected to motors or other apparatus, is to vulcanize them; but this entails considerable expense which in most cases is unwarranted. Consequently in these notes reference is made only to the well-known method of finishing off with rubber and adhesive tape. It is safe to say that in the majority of cases, the ends of rubber cables are improperly prepared before taping, and are seldom completed in a manner likely to reduce leakage to a minimum.

**PRINCIPLE OF INSULATION**

The principle on which the end of a conductor should be insulated and finished off, is that there shall be a sufficient break between the conductor itself and any moisture-conducting material, which may form a part of the insulating and protective coverings. These in the case of rubber-insulated cables consist first of a thin sheath of pure para rubber next to the conductor. Over this and vulcanized to it is a layer of rubberized tape which is covered by a very thin double layer of cotton fabric. Over this is placed the protective covering of braid or whipcord, the stoutness of which depends upon the conditions under which the cable has to work.

In Fig. 1 are shown the various stages in the preparation and finishing of a cable end that is being fitted with a terminal lug. The first part of the process is to bare the conductor as shown at A, care being taken to prevent the knife from cutting into and weakening the outside strands of wire. The outer braid should then be cut back a short distance, depending upon the size of the conductor, but not less than about  $\frac{3}{4}$  in. This will expose the thin cotton fabric which surrounds the vulcanized rubber insulation as shown at B. This thin cotton fabric should not be disturbed until after the lug has been sweated on to the conductor, as the fabric prevents the heat from expanding the rubber unduly when this is being done. After the lug has been

Fig. 1—Cable Ends Made Like This Will Not Leak

A. The first step in the preparation of a cable end consists of cutting back the insulation without injuring the wire. B. Shows the outer braid cut still farther back so that it cannot act as a wick and cause moisture to get at the wire. C. The terminal is now in position and a sufficient section of the wire is still exposed to permit the proper wrapping of tape. D. Rubber tape is wrapped partly over the terminal so as to form a long leakage path between the exposed surface of the terminal and the wire. E. After the adhesive tape has been put in place a coating of insulating varnish should be applied to the joint; this will effectively seal the layers of tape together.

sweated on and the thin cotton fabric has been removed, the cable end appears as at C, and in practice there should be at least  $\frac{3}{4}$  in. between the outer braid and the conductor. Thus, in the event of the outer braid being exposed to moisture this cannot work itself along to the conductor as the short length of rubber insulation intervenes. If the fine cotton fabric is not removed, moisture, after reaching the point at which the outer braid is cut off, continues along this fabric, at the end of which only the radial thickness of the rubber insulation is interposed between the moisture-conducting material and the conductor itself.

The cable end is now ready to be insulated. This should be done with pure para rubber strip. It should be wrapped tightly in order to eliminate air spaces, extended well onto the body of the lug and well past the point where the outer braid has been cut off. The cable end should then appear as at D, the rubber taping being applied until it

is slightly larger in diameter than the cable itself. The end of the rubber strip should be fastened down with solution. Adhesive tape should then be applied, starting on the outer braid of the cable covering and brought to within  $\frac{1}{2}$  in. of the end of the rubber taping on the lug, thus still preserving the break between all moisture-conducting material and the cable lug. The finished end is shown at E. A coating of varnish extending from the body of the lug to just where the adhesive tape ends, completes the work and makes an efficiently insulated terminal attachment. The foregoing is applicable to cables of almost any sectional area.

ELECTRICIAN.

## Drill Press Conveniences

The machine shop in the central shops building of the Island Creek Coal Co., Holden, W. Va., is equipped with two drill presses; one of these is shown in the accompanying illustration. The drill press itself is not different from the usual type, but an attachment to the drilling table in the form of a vise and a pit in the floor to one side of the base impart greater utility to the machine and facilitate its operation.

The vise is held by bolts in the retaining slots of the drilling table and is attached or detached with little effort. It serves for holding strap-iron and other objects of such shape that they cannot be conveniently held on the

Two Conveniences for a Drill Press

A vise on the drilling table and a pit on one side of the base facilitate the drilling of holes in many objects.

platen. The pit in the floor enables the drill operator to work with long angle-shaped objects by allowing one end to project into the pit.

### Hinged Track Enables Incline To Cross Railroad

Where a mine in a mountainous district lies at an elevation considerably higher than that of the tippie, it often is necessary to crowd the tippie against the hillside. Usually there is little or no level ground between the hillside and the railroad track for laying out a supply yard, in which case the incline leading to the mine must be provided with some sort of crossing over the railroad to connect it with a mine track leading to the supply yard.

#### BRIDGE SWINGS VERTICALLY

Such a condition prevails at the Gay mine of the Gay Coal & Coke Co., Mt. Gay, Logan County, West Virginia. The crossing of the mine track over the railroad is effected by a bridge track which swings vertically over the railway. One end of the bridge track is hinged at the foot of an incline supply tramway and the other end, when lowered across the railroad, connects with a turntable which can be revolved through 90 deg. to butt with the mine track leading to the supply ward. When not in use the bridge track is swung upward into the clear by a rope that passes from one of the steel ties on the bridge track, around a sheave on a timber set to a windlass.

#### A Successful "Bridge Track"

Because the railroad at the tippie lies between the incline and the supply yard at the Gay mine, a swinging bridge track that is hinged to the lower end of the incline, and connects with a turntable in the foreground, was constructed. This bridge track is raised and lowered by a windlass.

### Gas-Driven Generator For Emergency Power Service

Our company, like others, has often found itself in difficulties due to power interruptions. We take power from a public-utility line which serves many coal mines and other industrial plants in our region. We have been delayed

frequently because some one on the line would have an excessive overload and trip out the main circuit breaker. No doubt power-plant overloads line troubles, grounds and short circuits are contributing causes to our delays.

Whenever the power fails the fan stops and this necessitates much running around to call the men from the

working places and at the same time trying to determine how long it will be before service is restored. All operations stop when no power is available but over-head charges mount up unproductively.

If the power is off for an hour or more and then restored it is frequently a difficult task to get the workmen back to their places. Some already have left the mine because they have an idea that service will not be restored for a few hours and have consequently gone home.

To overcome these conditions we recently purchased a four-cylinder, 100-hp. gas engine. To this unit is connected a 68-kw., 440-volt generator which is connected to a double-throw switch. The power lines from the utility company are connected to one side of the switch and the wires leading from our generator are connected to the other side. Now, when the power company service fails the double-throw switch, normally connected to the power company's lines, is thrown over. This arrangement gives us ample power to drive our fan, of course, other machines are taken off the lines or they would overload our engine.

The ease and quickness with which our stand-by outfit can be started, eliminates the necessity for calling the workmen from their working places, in fact, in about three minutes after a power failure the fan is again started and running with energy supplied from our generating outfit.

JOHN ROUTLEDGE,  
Engineer.

Majestic Coal Co.,  
Majestic, Ala.

#### Gas Engine Drives Stand-by Generator for Emergency Purposes

Whenever the public-utility power fails this unit is started and supplies 440 volt energy for driving the mine fan. Now the workmen may continue with their work, until power is again restored. In this way each man is afforded every opportunity to do a full day's work.

## Problems In Underground Management

### Subsidence, How Far It Extends, Its Depth And Rapidity of Movement

Stretches Furthest Beyond Coal Face When Workings Advance to  
Dip—The Greater the Profundity of the Seam, the  
Less Pronounced the Sag

IN HIS testimony before the Royal Commission on Mining Subsidence, of Great Britain, T. A. O'Donahue, declared that subsidence theories were conceived and then facts were sought to fit the theories. He believed that the observations should be made first and then a theory be formed to accord with them. Mr. O'Donahue said that though he had experience in many fields, he had more intimate knowledge of conditions in Lancashire. He had commenced taking levels in March, 1901, and had continued at intervals of from three to six months from that date to the present time.

During that period, the effect on the surface of workings had been observed over an area extending several miles, the depths of the seams worked varying from 500 to 3,400 ft. In fact as ordnance (government) bench marks were generally available over the area evidence of the settlement was obtained by the first levelings. The surface is covered with a drift of extremely irregular depth, the thickness of which, where proved, ran from 40 to 60 ft.

#### BREAK TO SURFACE SLOPES BACKWARD

In the Upper Seam, which has workings from 500 to 2,500 ft. deep, a line drawn from the edge of the excavated face to the point where subsidence begins to occur at the surface would bear back over the coal face about 5 deg., where the inclination of the seam is about  $16\frac{1}{2}$  deg. With another working face in the same seam, however, subsidence did not extend beyond a vertical line. The difference may be ascribed partly to the steepness of the inclination of the measure (20 deg.).

In the Deeper Seam, which has workings from 1900 to 3,400 ft. deep, the subsidence also extends beyond the edge of the workings to the rise. The maximum angle of the point of "draw"\* beyond the vertical line is 8 deg. The greater angle in this case no doubt is partly due to the lower inclination of the strata. With workings to the dip the subsidence in all cases is found to extend not merely beyond the edge of

the workings but also beyond a line drawn from the edge of the workings at right angles to the plane of stratification.

In the Upper Seam, where the strata are inclined 18 deg., with workings at 1,940 ft. depth, the draw beyond the vertical was 23 deg., or 5 deg. beyond the right-angle line. In the Deeper Seam, with workings 3,000 ft. deep, the draw beyond the right-angle line extended 8 deg., but the inclination of the strata was 12 deg. only, so the total draw beyond the vertical line was 20 deg.

#### SURFACE SUBSIDENCE IS SMALL

The maximum subsidence produced by the Upper Seam was 1 ft. 9 in., where the seam was about 850 ft. deep. The seam at this point was 3 ft. 4 in. thick, and about 6 in. of warrant (worthless material) was excavated with the seam. As roads had to be ripped, the total thickness, in place, of the rock packed into the waste (exclusive of falls of roof) may be taken to average 10 in. over the whole area. The subsidence recorded in this area is exceptionally low compared with all other cases.

At a depth of 1,900 ft. the total subsidence was 1 ft. 6 in. The thickness of the seam at this point was 2 ft. 10 in. and the thickness, in place, of the packing material may be taken to average 10 in. over the whole area. In the Deeper Seam, with workings nearly 3,000 ft. deep, 1 ft. 5 in. of subsidence was recorded. The coal was 4 ft. thick and 1 ft. of fireclay was mined with the coal. As 2 ft. of ripping was taken down, the total waste packing may be taken as being equal to an average thickness of 1 ft. 5 in. over the whole area.

In no case does the full subsidence occur beyond the edges of the workings. In the Upper Seam this maximum is found nearly 900 ft. behind the face of the workings, which are on the rise side. With workings to the dip the full subsidence in one case is 600 ft. behind the edge of the workings. In the Deeper Seam, with the workings to the dip, the full subsidence is 550 ft. behind the edge of the workings. The regularity of the subsidence throughout the entire

area and the comparative rarity of distinct breaks has been due, no doubt, to the thickness of the alluvial drift at the surface. In consequence, extensive buildings over the area to which reference is made have suffered little damage.

Subsidence did not commence until two years after the date of working where the workings were 1,000 ft. deep and advanced to the rise at the rate of 160 ft. per annum. The subsidence then continued for ten years, when it reached the maximum of 1.31 ft. In the Deeper Seam, with workings 3,000 ft. deep, advancing to the dip at the rate of 200 ft. per annum, subsidence occurred 500 ft. in advance of the face and it required twelve years to give the maximum subsidence of 1.44 ft.

### Mine-Haulage Accidents Far Too Frequent

Complaint frequently is made that the haulage-accident rates in mines are inexcusably high. It is true that next to falls of rock and roof come accidents incident to underground transportation, but sight frequently is lost of the fact that half of the tonnage carried by the railroads of the United States first must be transported underground, in the dark and for the most part over temporary roadbeds. Underground hauls of 5 miles are not uncommon. To obtain the economies of quantity production, this haulage must be done at high speeds.

Many underground haulage accidents are due to poor roadbed. Though better roadbeds probably could be provided in many instances, account must be taken of the economic factor and the fact that only the main haulage-way will be used long enough to justify thoroughly substantial construction.

One of the difficulties in the study of these accidents arises from the absence of statistics. Despite the fact that more than \$600,000 annually is made available by the government for the study of safety in connection with rail transportation on the surface, no money has been appropriated for studies of rail transportation underground, which handles half as much tonnage. The Bureau of Mines has made some study of the matter, but the work has been limited by such small sums as could be diverted from the sums assigned to other branches of mine-safety work. The increasing rate of haulage accidents in mines is giving rise to a demand that the government give more attention to studies looking to their reduction or entire prevention.

\*Mr. O'Donahue apparently uses the word "draw" as meaning the point of remotest discoverable subsidence. As a matter of fact that would not necessarily be the point of remotest rupture.

## Rock-Dusting Car for Use At Springdale Mine

So conclusive has been the proof of the effectiveness of rock dusting to check coal-dust explosions that many bituminous mines are accepting it as standard practice. The use of rock-dusting prior to the time its feasibility was generally recognized was so limited that the problems of distributing it most expeditiously are only beginning to be solved. Nowadays a rock-dusting car in its early stages of construction, or completely built, is not an uncommon sight in mine shops.

The accompanying illustration shows a rock-dust distributing car throwing a cloud of dust in the open air. It was built in the machine shop at the Springdale mine of the Allegheny Pittsburgh Coal Co., Logans Ferry, Pa. The construction of the car in its present form is entirely experimental, it being the purpose of the company to determine the best principles upon which to base the design of the rock-dust distributing equipment that ultimately will be adopted.

### METHOD OF OPERATION

The car as shown is equipped with a Sirocco blower that develops about 1,800 cu.ft. of air per minute. It is driven by a 5-hp. direct-current motor. Rock dust is introduced into the blower through a funnel hopper with a fly-leaf valve feed control. The discharge is nothing more than a standard length of 6-in. stove pipe which is connected to the blower by a piece of flexible composition hose. The discharge pipe is moved up, down or to either side by a fulcrum bar to which it is attached by a chain-link coupling; this bar swings in a keeper after the fashion of an oar in the rowlock of a row boat.

It will be noted that the equipment is located on the rear end of the car. In all probability the blower later will be shifted to the front end of the car so as to leave room for a hopper behind it. Rock dust will be fed from the hopper

to the blower by a bottom screw feed. Of course a supply wagon will accompany the distributing car. The rock-dusting outfit will be pulled by a locomotive moving against the air current so that the dust will be carried away from the work trip which will always be in the clear.

## Nova Scotia Man Shows What Has Been Done

In the July 3, 1924, issue of *Coal Age* (Vol. 26, p. 22) a West Virginia Operator requests suggestions from mining men and engineers for the best method of working a somewhat peculiar coal bed. Although the operator making inquiry appears to consider the conditions difficult, I can hardly regard them as such, as I have had experience in mining a somewhat similar measure.

As several plans for working this coal bed have already been suggested I shall confine myself to describing briefly the method of operation with which I am most familiar. The coal bed to which I refer carried a 10-in. drawslate and the upper coal band was 4 ft. thick. An 8-in. rock parting occurred about 12 in. from the floor. In all there were three benches of coal and two of slaty material in addition to the drawslate.

If among these various strata a good mining ply occurs, places or rooms can be driven, say, 12 ft. wide, the mining being done with hand picks. Blocks or pillars 50 or 60 ft. square are left. This process of opening out is slower than by means of double rooms but it will prove more economical and efficient in the end, because when the pillars are being extracted the roof weight makes the use of mining machine unnecessary.

The general plan above outlined proved most advantageous for working the bed described. In some cases the pillars were brought back by longwall retreating, all the faces of a range of pillars being kept in line, while in others they were drawn in lifts. As soon as a lift is finished the roof behind

it is allowed to come down. The accompanying drawing illustrates the method followed.

When a section has been opened out to, say, 400 ft. square the work of extracting pillars may be started. This may be done as at A in the drawing or by working a single longwall face on the rear of the pillar. In such a layout as that shown the longwall face would be preferable because the rock and refuse produced in mining could be disposed of more readily. Experience in coal mining has demonstrated that when dirt occurs in a coal bed the only

Plan of Mining

This is practically a block system of operation instead of a room-and-pillar system. Only a comparatively small proportion of the coal will be secured in blocking out a panel, the chief source of output being the pillars.

satisfactory way of separating it from the coal is to pick it out. Its logical place is in the gob and not on the dump.

Hand operation—that is, pick mining—is advocated for working this bed. This may appear to some to be a somewhat antiquated practice, but it should be borne in mind that so far statistics have never proved conclusively that mining machines have lowered the cost of coal. I believe also that in most cases a far smaller proportion of the cost of producing coal is charged to transporting it from face to tippie and there loading it into the railroad car than would be justified if facts were honestly considered.

MAC.

River, Herbert, N. S.

Experience with mining machines has shown them extremely profitable both in reducing the cost per ton at the face and in increasing production and thus lowering handling charges per ton. They also have decreased the percentage of small sizes wherever hand mining had deteriorated, as in many places, to shooting off the solid. Undercutting is safer than the indiscriminate solid shooting likely to be employed where mining machines are not used. In most instances, however, union contracts have made the differentials for machine mining over extraction by hand so small that often no economy could be effected in the cost at the face by providing machines.

We are sometimes disposed to believe that mining men of British or other foreign extraction when on this continent are too ready to tackle problems like those they have faced abroad, wholly forgetting that in most parts of America there are so many clean beds that it is inadvisable to attempt the task of working less desirable beds which can be worked successfully only when operating for a market where competition is largely with coals mined under similarly unfavorable conditions.

—EDITOR.

Trying Out New Rock-Dust Equipment at Springdale

As will be readily seen this outfit is frankly experimental, being placed within the body of an ordinary mine car and mounted so that the dust must be carried in another car not easy of access. It will, at least, test the equipment. The problem of adjusting the car to the outfit will come later.

# Production And the Market

## Trend of Bituminous Coal Market Is Upward Though Course Is Irregular

The bituminous coal market continues to move irregularly, but the trend is unmistakably upward. Marked strength pervades the trade in New England, reflecting a pickup in the textile industry, but western Kentucky just now probably shows the greatest improvement. In Illinois and Ohio, on the other hand, "no bills" have appeared again, though Cincinnati is an outstanding exception, slack having become scarce there. Caution is in evidence throughout the trade, which means that competition is fairly keen.

### Healthy Undertone Indicated

Much light is thrown upon hitherto dark places by the government's report on commercial stocks of soft coal as of Sept. 1. Though the total reserves in the hands of consumers—47,000,000 net tons—is 4,000,000 tons less than on June 1 and 15,000,000 tons less than on Jan. 1, the supply would fall only one day short of lasting as long as the surplus at the beginning of the year, the disparity being due to the greatly decreased rate of consumption. The steady though gradual increase in demand and output despite the size of the reserves is indicative of healthy underlying conditions in the market.

Coal Age Index of spot prices of bituminous coal for the sixth consecutive time registered an advance last week, standing on Oct. 13 at 174, the corresponding price for which is \$2.10. This compares with 171 and \$2.07 respectively on Oct. 6.

A slight increase in activity was in evidence at Hampton Roads last week, dumpings of coal for all accounts during the seven-day period ended Oct. 9 totaling 340,447 net tons, compared with 331,398 tons handled during the preceding week.

Movement of coal across the lakes continues in good volume although it had been expected to fall away markedly by this time. Dumpings at Lake Erie ports

during the week ended Oct. 12, according to the Ore & Coal Exchange, were as follows: For cargo, 737,102 net tons; for fuel, 40,547 tons, compared with 731,604 and 45,145 tons during the previous week.

Anthracite is moving without much difficulty on the whole, stove being in rather strong demand, though chestnut is picking up noticeably and egg is holding its own fairly well. Steam sizes are in fair demand, No. 1

buckwheat showing notable firmness. Independent prices have occasioned much surprise, having soared 75c. above company schedule in some instances. Output is still greatly hampered by floods at the mines, which are even more serious than was at first supposed.

Production of bituminous coal continued to show improvement during the week ended Oct. 4, when, according to the Geological Survey, the estimated output was 10,268,000 net tons, an increase of 128,000 tons over the week ended Sept. 27, when 10,140,000 tons was produced, according to revised figures. On the other hand, there was a sharp decline in the output of anthracite, the total for the week ended Oct. 4 being 1,425,000 net tons, compared with 1,942,000 tons during the preceding week. The falling off was due to the water in the mines.

### Fine Coal a Drug on Midwest Markets

Continued mild weather has affected the Chicago market in so far that off-grades of southern Illinois domestic coal are looking for orders and may be had at somewhat reduced prices to get business, but only on egg and nut. Lump is firm in every field with operators hopelessly behind in making shipments. Some of the large operators in the southern Illinois field have found it necessary to close down because of unsold screenings, hoping thereby to stimulate prices. The tracks are full of "no-bill" fine coal in every district and it is a buyers' market.

From all indications retailers in the central northwest have delivered much coal to domestic users. Eastern Kentucky is firm and Pocahontas screened coal cannot easily be had. Dealers are showing a tendency to bid the price up. Anthracite is moving fairly well and is being rapidly consumed, but no change of price is indicated.

Southern Illinois is still short of lump coal, but egg is not moving as freely as it was a week ago. This is the condition in the Cartersville field although some mines are pretty well sold up on egg. Nut is still plentiful and the smaller steam sizes are heavy and are in the way. Some mines are unable to work on account of "no bills" but most of them are getting on an average four days a week. Railroad tonnage is light. In the Duquoin field conditions are similar to those of the Cartersville district. In the Mt. Olive

field there has been a good movement of all sizes. Most of the small sizes are going on contract and domestic sizes are moving well, as is railroad tonnage. In the Standard field it is still a guess as to whether the prices are bringing the cost. Conditions are unsatisfactory and many mines are idle and will not start up and those that are working have "no bill" steam sizes on hand.

Warm weather caused the St. Louis market to ease off a little this week. There is, however, a fairly good movement, most of it coal sold during the recent cool spell. In a domestic way, however, business is good from the country and for the better grades of coal principally. Two-inch Standard is not taking in the country district this year. As a matter of fact, Standard is hard to move to the country dealer. Locally steam shows activity, especially in wagon load.

### Many Kentucky Mines Oversold

The Louisville local market is in excellent shape, the jobbers' principal complaint being over inability to obtain deliveries from the mines, many of which are oversold. Prices are advancing steadily until the peak quotations in both eastern and western Kentucky are \$4 a ton on best grades of block, although there is not much eastern Kentucky at over \$3.50@3.75. Lump is \$2.50@3; egg, \$2.25@2.75; nut, \$2@2.25; mine run, \$1.35@1.75 and screenings, 85c.@1. Eastern Kentucky is operating on wage scales

Index	1924			1923
	Oct. 13	Oct. 6	Sept. 29	Oct. 15
Weighted average price	174	171	170	185
	\$2.10	\$2.07	\$2.06	\$2.24

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and send, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

equal to or below the 1917 level, for the most part, and is quoting under western Kentucky, which is asking \$3.75@ \$4 for block and lump; \$3@ \$3.75 for egg; \$1.90@ \$2.75 for nut; and \$1.50@ \$1.90 for mine run. Western Kentucky screenings are 75@90c. It has been reported that some eastern Kentucky screenings have sold as low as 75c. Movement is as full as operating conditions will permit, there being a good car supply and steady demand.

Northwest Markets Unruffled

Pocahontas lump is cutting heavily into the hard-coal business at Duluth. This is creating a serious situation in Pocahontas, as there is much of this coal on the docks in screenings form which cannot be disposed of. Prices are the same all down the line. Docks are loading out rapidly, but most of the coal goes to dealers and little is on its way to industrial concerns. The public utilities, however, are showing signs of life and may come in soon for some of the screenings. It begins to look as if there would be an oversupply of hard coal. Last week 28 cargoes arrived at this port, of which only one was hard coal. Sixteen are reported on the way from lower lake ports, and of these only two are anthracite.

In the Twin Cities no real progress seems to be made in the coal business with the advance of the season. Consumers insist that they can get fuel as they need it, and under the going market and refuse to stock to any extent. This does not seem likely, as a firm market bids fair to prevail for some time. Dock receipts are moderate, indicating that there is not likely to be any great amount received in the remaining weeks of navigation. Present totals

are about the same as a year ago, but the prospective market is greater. The all-rail trade continues to be in considerable of a change, due to the increase in rates on southern Illinois rather cutting off that market in favor of the other districts of Illinois and Indiana. But as yet the demand has been small, and it is something of a question what will happen when the rush begins.

Coal movement has fallen off at Milwaukee during the past week owing to weather conditions. Dealers report a freer movement by rail, but continued difficulty in getting West Virginia splint, Pocahontas and Kentucky coal. Pocahontas advanced at the mines to the extent of a dollar during September. All of this advance has not been reflected by the retail market, but Pocahontas is now selling in Milwaukee at \$11.25 for egg and lump spouted, and \$12 for the same grades carried in. Movement by lake continues free and steady. Receipts thus far in October total 108,019 tons—12,900 tons of anthracite and 95,119 tons of bituminous coal.

Western Domestic Demand Gains Momentum

Demand for domestic grades through the Southwest continues to grow stronger and the mines are working full time. But, as there has been no corresponding improvement in the industrial market, the surplus of screenings, noticeable the last two weeks, is mounting. No changes in prices have been announced.

Colorado coal seems to be moving at a fairly good pace now and with the advent of colder weather operators look for a busy and more lucrative season. Colorado mines worked on an average of 31 hours last week with 21 per cent of the working time lost attributed to "no market." Prices remain unchanged as of Sept. 1 and the supply of labor is sufficient. Transportation and car supply have been very good except in Routt County and the Trinidad district, where shipping of other commodities has caused a slight delay in the movement of coal.

Utah mines are increasing output, but operations still are far below 100 per cent of the full-time capacity; 55 per cent would be the outside. There is a shortage of slack coal, which some believe may become acute. Intermediate sizes are a drug on the market. Both retail and wholesale prices are unchanged.

Domestic Strong, Steam Draggly in Ohio

Many of the largest Cincinnati shippers and wholesalers are "sold up" either to the extent that they have practically nothing to offer or only enough free coal to care for the day to day turn of the market. Nut and slack residue and screenings are holding firm and in most cases show 5c. to 10c. advance in price. Domestic coals, however, have the center of the stage. Central Michigan, northern Indiana and the West were slow in getting into action but have come crashing in with orders. Steam coals are lagging, the range continuing between \$1.35 and \$1.65 for run of mine and 90c. and \$1.10 for screenings. The smokeless market has gone skyrocketing with the rest of the list. Under heavier buying orders practically all of the screenings that were held have disappeared.

Columbus trade is considerably one-sided. There is still a strong demand for domestic sizes, but steam business is slow and draggly. This has resulted in an accumulation of screenings, which have been selling extremely low, and causes the operator to hesitate before taking any further domestic business until he can find a place for the resultant sizes. On the whole the steam trade is not as strong as a week ago, but many producers are still booked up on orders and are running full blast, or at least as much as the labor situation will permit. Retail prices have advanced in sympathy with the higher domestic prices at the mines. Pocahontas and other smokeless grades are strong and little free coal is to be had. Lake shippers are closing up contracts after a rather good season.

Except for a continued strong domestic demand, the Cleveland market has experienced a slight reaction. Spot prices on No. 8 slack and nut and slack are off 5 to 10c. per ton, slack being quoted at \$1@ \$1.05, and nut and slack at \$1.10@ \$1.15, with softening tendencies. Retailers are active. Spot prices on Pocahontas lump have advanced during the past two weeks from \$3.50@ \$3.75 to \$5@ \$5.25 f.o.b. mines, and on West Virginia Panhandle splint lump from \$2 to \$2.50@ \$2.75 f.o.b. mines. The steam trade, however, is quiet and "distress" coal has appeared.

The Buffalo market hears much of the return of business activity all over the country, but does not see much of it,

as business is still dull. But for the increased output there is no doubt that the coal trade would be doing better now. The difficulty is that the operators anticipated this and have already killed the goose before she began to lay.

There is no noticeable improvement in the industrial demand at Toronto and movement is quite limited. Wholesale quotations are as follows: Steam lump, \$6.25@\$.65.0, slack, \$5@\$.5.25; Pennsylvania smokeless, \$5.75@\$.6.25.

### Pittsburgh Feels Stimulus of Cool Snap

Movement of domestic coal has increased rather sharply at Pittsburgh due to a cool snap. Offerings have been plentiful, however, so that prices have not advanced, although they are regarded as far too low, considering the value of domestic coal in the ground. They are much lower than last year. Current quotations are \$2.50@\$.2.65 for 14-in. lump and \$2.65@\$.2.80 for 2-in. lump. Considering the low prices of resultant slack and nut the realization is poor. Steam slack continues soft but is still quotable at \$1@\$.1.10. Gas slack remains at \$1.15@\$.1.35, but there is little going at over \$1.25. A few buyers, particular as to quality, are willing to pay \$1.35.

Production continues to increase in the central Pennsylvania field, 14,043 cars having been loaded during the first week in October, as compared with 13,973 in the last week in September. At Windber, where the Berwind-White operations are located, there is an upward tendency in operations. From three days a week, the company's mines are now operating four and some weeks five days.

### New England Market Still Forging Ahead

The New England tidewater bituminous market has advanced further with prices higher at the southern loading piers. The lowest at which strictly high grade run of mine New River and Pocahontas is now offered is \$5.40 gross ton on cars Boston, but \$5.50 is generally asked with shadings of more than 5c. infrequent. For late October shipments \$5.60 on cars Boston is named. After an early week softness, when some tonnage of New River was sold at less than \$5.35 on cars Providence, there has been a strengthening there too and \$5.40 is the minimum, with \$5.50 asked.

Local shippers have been unable to pick up really high grade mine run at less than \$4.25 gross ton f.o.b. Hampton Roads the past week and \$4.35 has been paid for a fair tonnage by one large local factor. With consumer demand expanding the market has assumed the greatest activity for months, a worth-while increase in textile operations having taken place.

There is little new in the all-rail situation. Sales are being made here and there, in one instance \$2.75 net ton mines having been obtained for a medium volatile extra lumpy coal. It is only in cases where extra lumpy coal is desired that Pennsylvania coal will interest buyers because even at the advanced prices at tidewater the landed cost of tide coal is under that of rail coal at most New England points.

### Demand Firmer in Atlantic Markets

The market at New York continues to go along without much change. Demand is a little stronger, but this has been met by heavier output, with the result that prices remain about stationary. There is a stronger tendency at tidewater and along the line. Consumers are more inclined to place orders and not so much disposed to question the price if they know they are getting good coal.

Fall business is well under way at Philadelphia and each day brings reports of industrial improvement, especially textiles, and these concerns are taking more interest in coal and are buying somewhat better. That all hands expect better market prices is shown in the care with which commitments are made, as there is an increased tendency not to take on big orders at current prices over an extended period.

The Baltimore market is ascending. Demand has increased from both large and small industrial groups and movement of coal from the mines is now running far ahead of that for October, 1923. Prices have not stiffened, however. The export situation is not as healthy as it should be for this season, the first ten days of October having dropped behind the same period of September.

Little change is reported in the Birmingham steam trade over a week ago. A good sprinkling of orders for spot coal continues—possibly a small gain over last week—but individual orders for substantial tonnages are rather scarce, even the railroads taking minimum allotments. The return of unseasonable weather quickly brought about a retrenchment in domestic buying. Quotations on steam and domestic coal f.o.b. mines are firm. Coal is moving better, production being higher than at any time in the last four months.

### Anthracite Plentiful Despite Flood

Considerable activity in the anthracite market at New York centers around stove coal, with a heavy call for chestnut. Buyers want stove almost exclusively but are asked to take either egg or chestnut with it and sometimes pea or buckwheat No. 1 is added. Consumption has not reached the point where retail dealers are hard pressed for supplies. Dealers' yards are filled to overflowing and they have large reserve stocks of egg and chestnut. Pea moves with some difficulty. Of the steam coals buckwheat No. 1 is the easiest, though rice and barley are in better shape.

Shipments to Philadelphia have been meager during the past week, as production has been greatly hampered by floods at the mines, which are even more serious than was at first reported. Since the cool spell retail trade has slumped. There was surprise when independents advanced prices 75c. above company schedule. Stove is the only size in strong demand, but even this is losing strength. Nut is becoming more popular.

Baltimore dealers report a fairly active demand. While some dealers are having trouble in getting all of the popular sizes they desire as ordered, the majority are able to meet the situation promptly. Most of the yards have fair supplies on hand, with coal running, and are keeping well abreast of their trade.

More coal is moving at Buffalo, but the demand is not large, as the days continue to be sunny and mild. There is all possible promise of a good supply of natural and by-product gas, but beyond that the consumer seems likely to be dependent on the regular anthracite supply for the winter. A few are using coke and finding it good, but sales are light.

## Foreign Market And Export News

### Inland Demand Active in British Market; Export Trade Depressed

Conditions are still far from satisfactory in the Welsh steam coal trade, though anthracite and dry steam coals are active and firm. The inland trade is showing the usual activity at this season of the year, but this is not enough to make much difference to the trade as a whole in the face of the acute depression in the export field. Demand from the Continent is particularly quiet. Shipments to France and Italy are low on account of the supplies of German reparation coal going to those countries. Welsh steam coal is quite unable to compete, and it is only in respect of contract deliveries and in cases where the highest quality coal is essential that the Welsh exporters are able to hold their own.

In a number of cases collieries are working only about half time and in several instances large collieries have been closed for a week at a time. The Bedlinog Collieries, employing 2,000 men, have stopped. Notices have been given at two collieries owned by Crayshaw Brothers, which will throw 2,300 men out of work at the end of a fortnight. Notices are expiring also in regard to some 3,000 or 4,000 other miners. Thirty-eight thousand miners are reported to be unemployed. Despite the fact that working costs are so much in excess of market prices, colliery owners have been compelled to make further reductions in quotations.

The general position of the Newcastle market is unchanged, with slight improvements in certain sections. Best steams are fairly steady, but the rates are weak compared with normal times. Small steams have been temporarily scarce, and for a time improved a little, but the firmness is due rather to the refusal of owners to make concessions than to any expansion of business.

Output by British collieries during the week ended Sept. 27, a cable to *Coal Age* states, was 5,210,000 tons,

according to the official reports. This compares with 5,135,000 tons produced during the week ended Sept. 20.

#### Coastal Trade at Hampton Roads Heavier; Prices Stiffen

Little change is perceptible in the activity at Hampton Roads. The market continues firm, with a slight increase in coastwise movement and bunker trade. Foreign movement is unchanged, with scattered cargoes for Italy, Brazil and other countries. Prices show a tendency to stiffen, indicating higher levels in the immediate future. Supplies at tidewater are dwindling to some extent in the face of heavier rail movements to the West and elsewhere.

General movement over the piers is on the increase and many good orders were reported in the trade for movement within the next ten days or two weeks.

#### French Industrial Inquiry Slow; Household Shipments Lower

Inquiry for industrial coals continues slow in the French market and wholesale prices hold to the level on Oct. 1, with the exception of industrial briquets, which have been reduced from 142.20 to 135.20f. The spread between British and French prices has been increased by the further rise of sterling.

Shipments of house coals from the mines are lower, as the merchants' autumn supply is now sufficient to meet consumer demand. Retail prices in the Paris market have been raised an average of 5 to 10f. per ton on September; anthracite nuts have been increased by 15f.

French imports of British coals are now nearer normal, but the quantities received for open sale from Germany are still weak. Shipments of sized coals

from Belgium are delayed through the rolling stock position there.

Deliveries of indemnity fuels from Germany to France and Luxemburg during the first twenty days of September were 610,700 tons, including 295,200 tons of coal, 297,500 tons of coke and 18,000 tons of lignite briquets, a daily average of 30,000 tons. Since Oct. 1, deliveries have been made under the Dawes plan.

During September the O.R.C.A. received 275,896 tons of coke, a daily average of 9,200 tons, as against 280,938 tons in August.

## News Items From Field and Trade

### ALABAMA

Work has begun on the addition of 25 Koppers byproduct ovens at the plant of the Alabama Byproducts Corporation, Boyles, for which the contract was recently awarded.

The Pratt Fuel Co., Birmingham, of which Walter Moore, 715 American Trust Bldg., is president, is reported to have acquired the coal lands, mines and leases of the Nelson Coal Corp., of which Frank Nelson, Jr., is president. This purchase includes 1,200 acres in Walker County and the Red Star mines and equipment.

The Moss-McCormick Coal Co. is opening new coal mines near Jasper. They will have five openings, the coal from which will be handled over one centrally located tippie. C. E. Crandall, superintendent, says that the total tonnage of this company will approximate from 2,000 to 3,000 daily when the property is fully developed. This company will build a railroad from the mines connecting with a spur of the Frisco Railroad. Employment will be given to 600 miners.

At the sixth annual Alabama first-aid meet, held at Rickwood Field, Birmingham, Oct. 7, three interesting events in first-aid work were staged and participated in by forty-nine teams. First prize was won by the white men's team of the DeBardeleben Coal Corporation, Empire (J. L. Shores, captain), which made a score of 99½ per cent, second prize going to the white men's team of the Woodward Iron Co., Bessemer, (W. E. Street, captain), with a score of 97 per cent. The ladies' teams from the Majestic Mines of the Majestic Coal Co., (Mrs. Geo. Rudd, captain) and a team from the Empire mines of the DeBardeleben Coal Corporation (Mrs. J. D. Sumners, captain) tied for the ladies' prize, the former winning in the run-off with a score of 97½ per cent. The winning colored teams were: First prize, Woodward Iron Co., Dolomite (Henry Dean, captain); second prize, Woodward Iron Co., Mulga (Chester Fuller, captain). These teams tied, the former being winner in the second trial, making a score of 96 per cent.

A new washery will be constructed and extensive changes and improvements will be made to the tippie at the Empire Mines of the DeBardeleben Coal Corporation, located on the Frisco Railroad, Walker County, involving an expenditure of approximately \$100,000, according to official announcement. The old washery is located some distance from the coal tippie, involving a switching cost at present, which the location

of the new washery will eliminate. Coal is mined at Empire from two openings, Nos. 1 and 2, on the Black Creek seam and is dumped at the same tippie, motor and tail-rope haulage being employed.

According to reports from the Walker County field the Galloway Coal Co. is considering the development of its Mill Creek properties, near Carbon Hill.

Coal mines are being opened at Altoona, Etowah County, on the Underwood seam by W. L. Smith and associates of Gadsden. A production of 400 or 500 tons daily is planned. A spur track and tippie structure are in course of construction.

The Birmingham agency of the Westinghouse Electric & Manufacturing Co. has been moved from the Brown-Marx Building to Rooms 1407-11, Age-Herald Building and advanced to a branch office with John Gelzer, Jr., as manager. The new quarters are much larger than the offices formerly occupied.

Contract has been awarded by Moss-McCormack Co. for the construction of a spur to its new developments near Carbon Hill, Walker County, on lands acquired from the federal government about two years ago. The track will be an extension of the Frisco Ry. spur to No. 11 Mine of the Galloway Coal Co., which connects with the main line at Carbon Hill. Stanley & Singer, of LaFayette, will construct the new line.

### ILLINOIS

The Lovington mine, near Paris, resumed work Oct. 1, after approximately a year of idleness. The mine is one of the largest in central Illinois. It was closed last fall because of lack of orders.

### INDIANA

A conference of mine workers' officials with representatives of the Knox Consolidated Coal Co. held Oct. 1 at the office of Phil Penna, secretary of the Indiana Bituminous Coal Operators' Association, failed to bring any solution regarding the division of work in the Bicknell field. The Knox company owns five mines in that field, only three of which have been operating. Those who had been employed at the idle mines asked that the company divide the work so the idle mines would operate part of the time. In the contracts the operators have agreed to a fair division of the work whenever business conditions permit. They explained to

the committee that business conditions are not such that the company can operate the two idle mines and that further division of the work is impossible.

### IOWA

Coal has been found on the August Witt farm, near Merrill, Iowa, a 15-in. vein having been struck by drillers at a depth of 415 ft. Another test will be made east of Merrill and if a satisfactory amount of coal is located, active mining will be begun.

### KANSAS

The campaign for complete unionization of District 14, United Mine Workers, recommended recently by two representatives of the International board, is under way. Osa Gasaway, International board member from District 8, and D. F. Frampton, of Moberly, Mo., an International organizer, are at work among the non-union miners of the district.

### MARYLAND

The Eastern Fuel Co., has opened an office at 638 Equitable Building, Baltimore, in charge of Hall Hammond.

### MINNESOTA

Bids for fuel for the county home and the Ancker City and County Hospital, St. Paul, were rejected a few weeks ago and new ones taken on a B.t.u. basis. Buying the old way resulted in a loss of nearly \$13,000, according to estimates by the City Chemist.

The County Board of Control in St. Paul has awarded contracts to the Northern Coal & Dock Co. for furnishing West Virginia splint for the county home at \$5.40 on track, and for the Ancker City Hospital at \$6.25 delivered. Both are on the B.t.u. basis of 14,100. Previous bids on a straight basis were rejected.

### MISSOURI

James Duncan, of Alton, Ill., was named permanent receiver for the St. Louis Coke & Iron Co. by Federal Judge Fitzhenry at Springfield, Ill., Oct. 6. Mr. Duncan, who is president of the Litchfield & Madison R.R., has been acting as temporary receiver for the company since Sept. 8, when a friendly receivership suit was instituted by the Iron Mountain Co., a creditor.

## NEW YORK

Will A. Brown, who is well known to the coal trade, having been engaged in the New York market for many years, has removed his office from 25 Beaver Street to No. 1 Broadway.

The request for offers to furnish slack coal to the Buffalo waterworks in 300- and 500-car lots brought out 17 bids, which were opened Oct. 6. Prices offered ran from \$3.47 to \$3.89 including mostly a \$2.24 freight rate. It will be some days before the lowest regular bid is fixed upon.

The New York Stock Exchange has stricken from the trading list, at the request of the Consolidation Coal Co. \$40,205,448 of its capital stock as a result of correspondence between the company and the listing committee regarding the issuance last spring of \$10,000,000 preferred stock, following which the stock previously outstanding became common stock. An amendment to the company's charter by the Maryland Legislature, required to make the change, was obtained after some delay.

When the war broke out the government took over the Donner-Hanna Coke Corporation's plant at Buffalo, then nearly finished and ran it as long as was desirable, then turning it back to the company, but never entirely relinquishing ownership. For this reason the private corporation has refused to pay taxes on it. On Oct. 6 Supreme Court Justice George E. Pierce decided that on account of the failure of the company to bring a certiorari proceeding in time, it will be obliged to pay \$130,000 in taxes and interest to the city and county.

## OHIO

Tom Dew, formerly vice-president of the Western Coal Co., has been appointed to represent the R. R. Smith Coal Co., of Huntington, W. Va., on the Cincinnati market. He will continue to retain his interest with the Humphrey Coal Co.

William S. Ranson and Delvin Orr, formerly identified with the Matthew Addy interests, have opened a wholesaling and jobbing concern in coal, coke, charcoal, pig iron and alloys in the Dixie Terminal Building, Cincinnati, under the name of the Ranson & Orr Co.

A petition has been filed in the Columbus courts, asking for the appointment of a receiver for the Consolidated Mining Co., a corporation, which formerly had offices at No. 8 E. Broad St. and which has since ceased to function as an active business. The petition was filed by the Central West Coal & Lumber Co., which holds an unsatisfied judg-

ment of \$9,462 against the defendant company. In the suit Henry Watkins and Albert Goff, president and vice-president, respectively, of the Consolidated Mining Co., were made co-defendants.

Coal men generally extended their condolences to Fred Legg, president of the Logan & Kanawha Coal Co., Cincinnati, whose father died at Montgomery, W. Va., on Sept. 26. His father, Richard Legg, had long been identified with the coal and railroad interests of the Mountain State.

J. T. Dunnigan, who for several years has been identified with the Harlan Kileoka Coal Co., at Harlan, passed through Cincinnati on Sept. 30 to take charge of the Coal River Collieries, owned by the Brotherhood of Locomotive Engineers. He will have general charge and supervision of these properties.

It was announced by officials of the Ohio Collieries Co., New Lexington, recently that Mine No. 256, at Glouster, and Mine No. 281, at Modoc, would reopen soon giving employment to about 600 men. The two mines have a daily capacity of 4,200 tons of coal and are the largest in the Hocking field.

Operations were resumed Oct. 9 at the Blue Rock Mine, located in Muskingum County, near the river bearing that name, for the first time since the disastrous flood of 1913. Following the flooding of the workings the mine was sealed and only recently Jerome Watson, head of the Ohio Mines Department, and a number of deputies explored the mine and has put it in shape for working. The mine is one of the oldest on the Muskingum River, having been opened in 1845, when the product was shipped by river exclusively. A squeeze occurred in 1854, when four miners were entombed and a new opening was made at that time. The gas formed to such an extent in the mine before it was opened by the mine department that it burst through the hill a few months ago.

## OKLAHOMA

After only a few days of quiet, hostilities were reopened in Oklahoma on the night of Oct. 6, when gateways to Mine No. 12, of the Rock Island Coal & Mining Co., near Hartshorne, were dynamited, and an attempt was made to burn two railroad trestles leading to the mine. The mine, which employs 350 men, has been operating part time. The company has been paying the 1924 wage scale approved by the union at its No. 12 mine, but had announced its intention to reopen other mines on an open-shop basis paying the 1917 scale.

## PENNSYLVANIA

The mine and other coal property of the Hess Coal Co., near Punxsutawney, was sold at auction on Oct. 1, being bid in by Scott Calderwood, one of the creditors and a stockholder in the company, for \$27,000.

The Somerset Realty Co. has purchased the Koontz farm, near Somerset, Somerset County, and has opened a coal mine. The company will be known as the Somerset Springs Coal Co. and the product will be known as "Coffee Springs Coal." The officers of the new concern are David Goodstein and W. Curtis Truxal.

A new service for members of the United Mine Workers in District No. 2, which includes fourteen counties in central Pennsylvania, was inaugurated recently when a compensation department was opened in Johnstown. Attorney Peter Jurchak has been named superintendent, with offices in the United States National Bank Building. This department has been under consideration for eight years and was finally authorized at the convention in Altoona early this year. The department will serve members of the union of all fourteen counties in District No. 2, which are included in the jurisdictions of these compensation referees, as follows: Jacob Snyder, of Altoona; W. W. Champion, of Williamsport, and G. Scott Smith, of Kane. The district includes these counties: Cambria, Somerset, Bedford, Blair, Clearfield, Huntingdon, Centre, Indiana, Armstrong, Jefferson, Clarion, Elk, Cameron and Tioga.

After pumping out the water in the old No. 5 anthracite slope at Silver Brook, the John C. Haddock Coal Co., which is reclaiming the operations after an idleness of over thirty years, expects soon to increase its tonnage from the local breaker. Free access now is afforded to sections of the mine which were submerged. A large force of men is working and additional employees will be taken on soon, it was announced. Silver Brook, formerly operated by J. S. Wentz & Co., was closed and abandoned when a disagreement arose over the terms of a new lease. The lessees are erecting homes for their men who desire to live near the mines.

## UTAH

J. A. Stallings, sales-manager for the Spring Canyon Coal Co., Salt Lake City, who had been ill for some months and returned to his desk recently has had to lay off again.

H. F. Fernstron, manager of the Western Fuel Co. and president of the Utah-Idaho Retail Coal Dealers' Association, has been selected chairman of the advertising and publicity committee of the Salt Lake City Chamber of Commerce.

B. W. Dyer, district engineer of the U. S. Bureau of Mines in Utah; State Coal Mining Inspector John Crawford and other officials will soon begin an investigation of the explosion at the Rains mine of the Carbon Fuel Co., this

Wardell Court.

A Square in Front of Union Pacific Coal Co.'s Club, Rock Springs, Wyo.

city, which resulted in the loss of five lives and wrecked the mine. Mr. Dyer said that the investigation had not been commenced yet because the ventilation had not been restored. He hoped, he said, to be able to issue a report about Oct. 11. Mr. Crawford completed an inspection of the mine about one week prior to the disaster and pronounced it safe. A. H. Jenkinson, secretary-treasurer of the company, declared that all of the new mine safety regulations of the Industrial Commission had been complied with.

## WEST VIRGINIA

The Buffalo Thacker Coal Co. has disposed of three of its mines at Ottawa, on the Chesapeake & Ohio Ry, and one mine at Chattaroy, on the Norfolk & Western Ry. It is understood the Eastern Coal & Export Co. was the purchaser.

James L. Crawford, of Page, and Joseph A. Graft, of Beckley, civil and mining engineers, have opened offices in Oak Hill. Mr. Crawford, who will be the chief engineer at the Oak Hill offices, formerly was chief engineer for the Loup Creek Collieries Co. at Page, and has had 12 years' practical experience in addition to his courses in civil and mining engineering.

The Diamond Fuel Co., in the Scotts Run field, has posted notices at its Liberty plant that hereafter the 1917 wage scale will be paid. Fifteen families were evicted during the first ten days of October. Although a number of men and women have congregated around the plant since the company first posted notices, there had been no outbreak of any kind at last reports. Six companies in this field either have resumed operations on an open-shop basis or are preparing to do so. They are the Diamond Fuel Co., the Continental Coal Co., Bunker Coal Co., Shriver Coal Co., Brady-Warner Coal Corporation and the Chaplin Collieries Co.

## CANADA

Nanaimo, B. C., is this year's winner of the Montizambert Cup, emblematic of the Canadian first-aid championship. Second, third and fourth positions were taken by Coleman, Alta.; Montreal, and Ottawa, Ont., respectively. In the Coderre Cup competition, open only to miners' teams, Nanaimo took second place, first honors having been won by Canmore, Alta. Another notable victory for Nanaimo was in the Wallace Nesbitt provincial junior competition. Fernie, Trail, Vancouver and Victoria followed in the order named. For the Lady Drummond Challenge Cup the Nanaimo ladies' first-aid team carried off second honors, being outpointed by representatives of the City of Montreal. The Ottawa ladies were third. The prizes were presented by Lieutenant Governor W. C. Nicholl.

Coal production in British Columbia, while not as heavy as in previous summer seasons because of the strike in the Crows Nest Pass, has been maintained at a fairly high level in the

Vancouver Island and the Nicola-Princeton fields. In June it was 135,872 tons; in July 146,217 tons and in August 131,284 tons. That the output should have advanced in July and dropped in August is a little out of the ordinary and is hard to account for. Statistics for the months of July and August show that the production of the Canadian Collieries (D), Ltd., and of the Western Fuel Corporation, Ltd., the two largest collieries of the island, has fallen to the extent of some thousands of tons. Other island collieries, however, have been advancing their output slightly, chief among these being the Granby Collieries and the Nanoose Collieries. The July output in the Nicola-Princeton District was 18,788 tons while that of August was 17,565 tons.

The mine managers of the Dominion Coal Co., Ltd., of Glace Bay, N. S., that are to make an educational trip through the principal coal-mining districts of Pennsylvania, West Virginia and Illinois are Daniel J. McCuish, manager of Dominion No. 1B mine; Billy S. McDonald, manager of Dominion No. 2; J. R. Dinn, manager of No. 4, and Tom J. Casey, manager of No. 11 mine. They will start on the trip within the next two weeks. The proposal of J. E. McLurg, vice-president of the British Empire Steel Corporation, Ltd., with the co-operation of Harry J. McCann, general manager of coal mines of the Dominion Coal Co., Ltd., to inaugurate a series of educational trips for representative men of the various departments of the steel company and the coal company, and associated companies, was well received by the general personnel of the corporation.

Total output of coal from Canadian mines during 1923 was 16,990,571 net tons, as compared with 15,157,431 tons in 1922, or an increase of 12 per cent, according to the official government report just issued. The previous high record, 16,946,764 tons was made in 1920. The value of the coal output in 1923 was \$72,058,986, or an average of \$4.24 per ton. Higher values were recorded in 1920 and 1921. Compared with 1922, the 1923 total value was an increase of \$6,540,489. Alberta had an output of 6,854,397 tons; Nova Scotia followed with 6,597,838 tons, while British Columbia produced 2,823,306 tons. The latter province and New Brunswick, which accounted for 276,617 tons, showed slight decreases from the quantities produced in 1922. Saskatchewan increased its production to 438,100 tons during 1923.

## Trade Literature

**Hi-Test Sucker Rods.** Marion Machine Foundry & Supply Co., Marion, Ind. Folder describing the different rods manufactured by this company.

**Blacker Hammers.** Blacker Engineering Co., Inc., Grand Central Terminal, New York City. Pp. 8; 7 1/2 x 10 in.; illustrated. These hammers travel over the anvil face, performing hand-forging operations and utility smithing without helpers.

**Little Giant Electric Hammer Drill.** Chicago Pneumatic Tool Co., 6 East 44th St., New York City. Bulletin 896. For use in drilling concrete and soft stone as well as for light chipping of metals. Equipped

with a Universal motor and will operate interchangeably on direct or alternating current. Illustrations of the drill are shown in this two-page bulletin.

**Walter A. Zelnicker Supply Co.,** St. Louis, Mo., in Bulletin 326, gives information on rails, including switch material and track accessories; cars, locomotives, shovels, cranes, etc.

**"National" Pipe for Power Plants.** National Tube Co., Pittsburgh, Pa. Pp. 51; 8 x 11 in.; illustrated. Among the data included are standard specifications for power piping; weights, dimensions, etc., of various classes of pipe and fittings; information on bends, pipe columns and hand railings; articles on steam, superheated steam and flow of steam; tables of various data of interest and help to those engaged in power-plant design and operation.

**Automatic Station Control Equipment.** General Electric Co., Schenectady, N. Y. Bulletin 47,731. Pp. 27; 8x10 in.; illustrated. Briefly describes the uses and advantages of this type of equipment. List of installations up to Jan. 1, 1924, is included, giving names of companies, stations, types of apparatus, kilowatt capacity and incoming and outgoing voltage.

**Turbo Waughammer, Model 37.** Denver Rock Drill Mfg. Co., Denver, Colo. Pp. 15; 6 x 9 in.; illustrated. In addition to fast drilling, ease of handling and ability to drill deep holes in any class of ground, this hand hammer, on account of its unusual rotative power, due to the drill still being rotated independently of the hammer action, eliminates the danger of "stuck steel."

**The Automatic Control of Combustion.** Carrick Engineering Co., Chicago, Ill. Catalog 99. Pp. 32; 8 x 11 in.; illustrated. Discusses automatic control methods and systems, bringing out the limitations of the various systems and why they fail. Analyzes the conditions to be met in coordinating supply of steam with the demand and gives some interesting charts of steam pressure.

**Systems for the Automatic Control of Combustion.** Carrick Engineering Co., Chicago, Ill. Bulletin M. Pp. 16; 8 x 11 in.; illustrated. Complete specifications, together with diagrams and list of equipment required for thirty-three distinct methods of automatically controlling boiler-room equipment, are given. Thirteen different methods of controlling powdered coal are included. Each method is illustrated and described and the apparatus necessary listed.

## Traffic

### Indiana Chamber to Fight On For Lower Rates

A second strenuous fight for lower and equalized freight rates on coal shipments is to be made by the Indiana Chamber of Commerce in behalf of Indiana manufacturers and other coal consumers. Testimony in the chamber's second eastern bituminous coal case will be heard before an examiner of the Interstate Commerce Commission at 10 a.m. Friday, Nov. 28, in the Federal Building at Indianapolis. All railways carrying coal to Indiana consumers from mines in Kentucky, Tennessee and West Virginia are named as defendants.

The State Chamber was led into taking up the fight for Indiana consumers by the action of manufacturers of the Kalamazoo and Grand Rapids (Mich.) belts, who brought action for a cut in coal rates that would assure them rates equal to those enjoyed by Toledo, Jackson and Detroit, it was said.

Indiana and Illinois coal-mine operators have intervened in the new case, which, the chamber promises, in the end will be for their better interests.

### Finds Indian Creek Valley Ry. Rates Unfair

Contentions on the part of the Indian Creek Coal & Coke Co. have been upheld by Interstate Commerce Examiner Fleming, who recommends that the commission find that existing rates from points on the Indian Creek Valley Ry. to Eastern and New England destinations are unduly prejudicial. Examiner Fleming proposes that the commission issue an order that rates from mines on the Indian Creek Valley Ry. "are and for the future will be unduly prejudicial to the complainant and other coal operators on that line and unduly preferential to the competitors of these operators in the Meyersdale region [Somerset County, Pennsylvania] to the extent that they exceed or may exceed the rates on like traffic contemporaneously maintained from the Meyersdale group to the same destination."

## New Companies

The Blue Banner Coal Co., of Jackson, Ohio, has been incorporated with a capital of \$10,000 to mine coal and deal in coal and coke. Incorporators are David Armstrong, Allen M. Rowe, Arthur L. Rowe, John M. Martin and A. J. Welch.

A Dominion charter has been granted the Northwest Coal & Iron Co., Ltd., with headquarters at Toronto. The company, which has an authorized capital of \$1,000,000, will carry on business as coal and mining operators. The following are named as incorporators: J. J. Butterfield, Edmonton; A. D. McDougall and F. H. Honeywell, Ottawa; S. G. Butterfield, Riverdale, Md., and E. C. Taft, Alliance, Ohio.

R. A. Brown, in association with some well-known operators of the Harrison County field, has organized the R. A. B. Coal Co., the headquarters of which are at Morgantown, with a capital stock of \$50,000, with a view to operating in northern West Virginia counties. Associated with Mr. Brown in the new concern are W. S. John, of Morgantown; V. E. Gocke,

Katherine Gocke, and Maud Brown, all of Clarksburg.

The Cameo Coal Co. has been incorporated in Henryetta, Okla., by R. R. Fretwell, of Henryetta, and E. R. Jones and L. W. Randolph, of Muskogee, Okla. The capital of the company is \$10,000.

The Combined Coal Co., a co-operative concern has been organized at Crooksville, Ohio, by 16 miners with a capital of \$42,000. The company has leased the Cres Mar mine, near Crooksville, which is a going concern. George Appleman is president; Harvey Smith, vice-president; and Fred Reed, secretary-treasurer.

The following coal companies were recently incorporated at the State Department, Harrisburg, Pa.: Lincoln Coal Co., of Scranton; capital stock, \$60,000; incorporators, David M. Thomas, 1134 Van Deventer Boulevard, Scranton, treasurer; David Lloyd, Scranton, and Herbert L. Williams, Scranton. Crafton-Ingram Coal Co., Crafton, \$25,000; incorporators, S. Harvey Fisher, 21 Hawthorn Avenue, Crafton, treasurer; William L. McCoy, Ingram, and Joseph A. Pannabaker, Ingram. M. K. Piper Coal Co., Kregar, Westmoreland County; \$100,000; incorporators, W. L. Piper, Lilly, treasurer; M. K. Piper, Lilly, and J. William McCauley, Lutherville. The Bituminous Coal Co., Inc., Philadelphia, \$25,000; incorporators, William F. Ehlers, 4372 Manayunk Avenue, Philadelphia, treasurer; Miriam S. Cramp, Philadelphia, and W. E. McCall, Jr., Bryn Mawr. The Clymer Moshannon Coal Mining Co., Clymer; capital \$20,000; incorporators, Charles E. Faust, James St. Clair, Peter Harr, Clymer.

## Association Activities

The Alabama Mining Institute held its annual meeting at the Hillman Hotel, Birmingham, Oct. 7. The annual reports of Frank Nelson, Jr., president, and James L. Davidson, secretary of the Institute, reviewed the work of the past year and revealed material progress in the aims and activities of the organization. The election of three directors to replace a like number whose terms expired resulted in naming Carr McCormack, of the Pratt Consolidated Coal Co.; J. L. Brierton, of the Central Iron Co., and Milton Fies, of the DeBardeleben Coal Co. Officers for the ensuing year will be named at a later meeting of the directors, the present officials probably serving for another year.

## Obituary

W. A. Garrett, chief engineer for the Bellick Knob Coal Co. at Meadow Bridge, W. Va., was instantly killed in an automobile accident early in October. Mr. Garrett was on his way to Charleston, where his family lived, when his car skidded on a muddy road and went over an embankment. Mr. Garrett, who was 46 years of age, is survived by a wife and eight children. Interment took place at Clendenin.

Henry Tennington, age 60, well known coal operator of Glen Campbell, Clearfield County, Pa., died in the Clearfield Hospital on Sept. 27. He was a native of Clearfield County and was interested for many years in mining in Clearfield and Cambria Counties.

## Coming Meetings

Illinois Mining Institute. Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

American Society of Mechanical Engineers. Annual meeting, Dec. 1-4, Engineering Societies Building, 29 West 39th St., New York City. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

West Virginia Coal Mining Institute. Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

Coal Mining Institute of America. Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers. Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

## New Equipment

### Speed Reducer with Novel Features

High-speed turbines and motors, which are rapidly coming into general use because of their compactness and economy, require a speed reducing mechanism when driving low-speed machinery such as compressors, generators, refrigerating machines, pumps, conveyors, crushers, etc. The ideal speed reducer should transmit the load

### Noiseless and Safe Speed Reducer

Housed where dirt and dust cannot get into the gears, the life of the reducer is greatly prolonged.

noiselessly, without shocks or loss of power, and should be compact and require little attention.

A speed reducer recently was developed by the Meachem Gear Corporation, 122-142 Dickerson St., Syracuse, N. Y., that meets these requirements in a novel manner. The load is transmitted from the high-speed shaft through planetary gears to a slower rotating annular ring. Inside this ring are connected a number of rockers which engage with a spider keyed to the low-speed shaft.

As the driving motor or turbine starts up, each of the rockers engaging with the teeth of the spider first compress a spring plunger which brings the bottom of the rocker into positive contact with the inside of the annular ring and at the same time brings its side

### Planetary Gears Transmit Power

Shocks are prevented by means of rockers which gradually pick up the load.

into positive contact with the side of the adjacent spider tooth.

During the time required to compress the spring plungers, corresponding to about one-quarter of a revolution, there is practically no load on the turbine or motor, and the load is then transmitted gradually and without starting shock. The spring plungers also serve to eliminate vibration and backlash, thereby assisting in promoting quiet operation.

#### PERFECT TORQUE ASSURED

The low-speed shaft to which the spider is keyed is supported on both sides of the spider. The pinion on the high-speed shaft is allowed to float and adjust itself to the proper position between the planetary gears, thus preventing side strains or unequal stresses and assuring perfect torque.

The speed reducer is totally inclosed, so as to be dustproof and foolproof, and all parts run in oil with forced lubrication on units operated at speeds above 1,800 r.p.m. The reducer can be applied to either step-up or step-down speed change, and is furnished in ratios from 4:1 to 200:1 and for any load up to 500 hp.

### Oil Circuit Breaker Meets High-Duty Requirements

A new line of outdoor oil circuit breakers has been placed on the market by the Condit Electrical Manufacturing Co., South Boston, Mass.

These are designed for 337,000-, 50,000- and 73,000-volt service, having standard capacities of 400, 600 and 800 amperes, and suitable for interrupting capacities as high as one million kva.

This new type breaker is constructed of steel and equipped with high-grade bushings and ample sized current-carrying parts, insuring a high degree of mechanical strength and providing exceptional insulating qualities. The highly-accelerated tripping mechanism and special contact design afford high-speed circuit interruption.

All breakers can be equipped with mechanisms for operation either elec-

trically or manually. The heavy-duty solenoid for operating the breaker electrically is inclosed in a steel housing with sufficient room for the relays generally used for overload protection. For automatic reclosing service, the automatic reclosing mechanism is furnished to operate either from direct or alternating-current circuits.

### Fan-Engine Regulator Controls Speed Automatically

The fallacy of the straight-line chart, of keeping boiler pressure constant, especially where there is a wide variation in demand, has been pointed out and

an improved fan-engine regulator that is extremely accurate and sensitive, controlled by varying boiler pressure and bringing about compensating changes in fan or blower speed smoothly and evenly.

#### DETAILS OF REGULATOR

In the illustration the boiler pressure connection and diaphragm, with a self-aligning hardened steel knife-edge bearing mounted on it, are unbolted and dropped down from their position in the device. Boiler pressure is at all times effective on the under side of the diaphragm. It is counterbalanced by the weighted beam which transmits the pressure change impulses through

#### Regulator Changes Speed Smoothly

The boiler pressure on the underside of the diaphragm transmits motion to the balanced beam, which is adjusted to the particular steam requirements. As the steam pressure changes the fan engine speed is regulated to deliver more or less air.

generally agreed upon. The exact amount of steam required to drive the fan engine or blower is seldom known and it is seldom clear just what exact change in boiler pressure should be required before the regulator is opened fully and the fan engine brought from normal to full speed.

With these ideas in mind the A. W. Cash Co., Decatur, Ill., has brought out

a link to the balanced valve which supplies steam to the fan engine.

Any decrease in boiler pressure causes a downward movement of the beam, an increase in valve opening, and therefore a gradual, smooth pick-up in fan speed. An increase in boiler pressure decreases the valve opening and lowers the fan speed smoothly and evenly to normal fan speed when normal boiler pressure is reached. Each definite change in boiler pressure is therefore accompanied by a definite change in fan speed, which will be repeated every time.

Assuming that good engineering requires an operating range of, say, 6 lb. on a certain installation, if the desired normal boiler pressure is 180 lb., the fan engine should be idling at that point and for economical reasons should be brought up to full speed only when the boiler pressure drops to 174 lb., should it fall that low. There should be a lag between the boiler-pressure curve and the fan speed curve.

With this device the amount of valve opening for a given change in pressure may be determined by the position of the valve in relation to the beam. The valve connection may be shifted along the positioning pad and the connecting link connected to the beam at the corresponding hole. In this way a definite, fixed amount of valve travel may be established in relation to a definite, fixed and scientifically desirable change in boiler pressure.

#### Large Oil Breaker Ruggedly Built

This switch may be equipped with suitable apparatus to make it automatically reclose. It may also be arranged for manual or electrical operation. An indicator connected with the switch mechanism shows when the switch is opened or closed.

## "Mud Slinging" That's Worth While

SOME OF OUR good friends who do not believe in "mudizing" are disturbed lest *Coal Age* advocate this "silly slopping around of dirty water" in mines. They shouldn't become so exercised until the coal industry learns more about this Rocky Mountain development in mine protection against coal-dust dangers. We are not prepared to say that "mudizing" is the thing, and neither is anyone else, not excepting even the developers of the process. However, no mining man who sees the results goes away condemning it.

We are willing, at least, to say that it is advantageous that so much attention has been centered on the rock-dusting problem that this new scheme was conceived. That, in itself is a wholesome symptom for coal mining. As to "mudizing," there is no denying that it has virtues. The thin mud mixture fills crevices and rounds off tiny ledges, thus positively reducing the opportunity for coal dust to collect. That alone is enough to make it a valuable practice, especially in dry mines. Perhaps "mudizing" will form so effective a base upon which to build a dry dusting system, that it will win its way into every well protected mine. At any rate exhaustive experiments with mud should certainly proceed. The coal industry should quickly learn all there is to know about this practice.

## One More Laugh

MR. PIN CUSHION, the gifted editor and publisher of the weekly *Squirt*, issued as second-class matter at Washington, D. C., under the pure food and drugs act of June 30, 1908, is all worked up again. The Canadian Government is about to take 20,000,000 tons of coal business in the eastern provinces away from American producers and give it to the Canadian mines by guaranteeing to just about pay the freight on the coal if the mines can't sell it any other way.

Would you believe it? Pin can prove that this is all Mr. Hoover's fault. Mr. Hoover's Department of Commerce which, Pin grieves to say, will receive \$3,400,000 this year with which to pay its useless expenses, has "been foster father to the very regulatory proposals which frightened Canada out of our markets," so Pin says. Therefore Canada fears it cannot depend upon the United States for a regular supply any longer. So it will depend, rather, upon its own Maritime Province mines. Just how a subsidy of five mills per ton—or "just about enough to pay the freight"—is going to keep those wild-eyed miners in eastern Canada on the job is too thick for us. But never mind. That's the case anyhow. Pin has spoken and Mr. Hoover is to blame for everything; take Pin's word for it.

What surpasses our mediocre understanding is this: Why has Mr. Cushion been so ready to figure out crimes to charge against Mr. Hoover? All Mr. Hoover ever did was to shut the door of the Department of Commerce to a man who would not be square with ideas

Mr. Hoover expressed in interviews. So why all this hectic flush every week? Well there is one good reason. The coal industry likes a laugh as well as anybody.

## More Permanency; Less Make-Shift

IT IS A regrettable fact that most electrical and mechanical installations and repairs made inside the mines are carelessly done. Some men often say, "It's good enough for the mines," whenever a job is criticised as being unsatisfactory, or executed in an unworkmanlike manner.

The use of more machinery and larger quantities of electrical apparatus is economically demanded by the mines of today. Each new piece of equipment makes everyone from the miner to the official more dependent upon its successful operation. When a motor, pump, controller or even a signal fails, someone usually must stand by idle. Occasionally the failure of even a small piece of equipment will shut down a whole mine.

Poorly installed apparatus is always a liability; dangers and accidents multiply when machinery that is loose, improperly installed and in disrepair is allowed to be operated. Savings theoretically attainable are often lost because a machine has been incorrectly assembled.

Most companies need to standardize some of their apparatus and to employ men who realize the growing dependence of the entire organization and plant upon the mechanical and electrical equipment installed. The days of makeshifting are about ended.

## Now It Can Be Told Best

WE NOTE WITH REGRET the collapse of many sectional plans for "coal institutes" which were going to tackle the job of educating the public about coal. The truth about its production and training in its economic consumption are two classes of facts the public ought to have. As J. C. Brydon said, when he retired from the presidency of the National Coal Association last spring, "The public's interest in coal seems quiescent just now but it might become active at any time." Just so. By the time the next Congress assembles at Washington, a rebellious sentiment in that body might well be active enough to force through destructive coal legislation, unless public sentiment is against such action.

Some contend that it is well to let the public forget the subject entirely and that, therefore, the less said now the better. To us this seems like clinging to public-be-damnedism. The more the people of this country know about coal all the way from face to furnace, the better. If there is anything it should not know, that thing ought to be trimmed out of the industry at once, if not sooner. We believe the truth about this industry can profitably be told and that it ought to be told now above all other times.

In years gone by, every time the industry has made

a concerted effort to tell the public about coal, the economic and political situation was such that coal was in ill repute the country over. Therefore, the lesson in coal was offered just when public acceptance was hardest to win. Why wait until the industry is on the defensive? That isn't good salesmanship. Why reserve all our selling effort for a time when the salesman has to break down the customer's locked door in order to get his all too hostile attention? He can walk in with a smile now, because the price of coal never was lower, considering the cost of production.

"But we can't afford it today," says a big part of the suffering industry. We admit that is a reasonable plea. But which is the better business policy: Spend a little money and effort continuously to prevent the regular and inevitable recurrence of fire, or wait until it roars down upon us and then throw in ten times as much for protection and maybe lose it all?

### Coal Claims Credit

COAL has a perfect right to claim credit frankly for aiding materially in the autumn industrial prosperity. And it ought to do so. It always has been easy for the country to blame assorted industrial ills upon high coal prices. Let the country now recognize the fact that, in proportion to the cost of production, coal has never been cheaper than in 1924. There is no better gage of the trend of coal prices than *Coal Age* index which is computed each week from the spot prices of fourteen principal American coals on the main markets of the nation "weighted" with respect to sizes and volume of production. The average coal price this week is \$2.12. A year ago this price was \$2.25. On Aug. 4, when summer conditions still prevailed, it was \$1.98; on April 1 it was \$2.09 and on Jan. 1, \$2.17. Not since before the war has the country seen such low prices.

A wise and well-known coal operator, talking before the executive heads of a great coal-consuming industry in Chicago last summer, remarked that great industrial advances the world over have been based on low-priced fuel and that the coal operator today recognizes that low-priced coal is necessary henceforth in this country. He said, however, that the operator cannot continue selling his product below the cost of production for that would rot the foundation of all industry.

This man admitted that all too little progress has been made in the past in cost reduction. This he said, has been chargeable largely to labor opposition and discouragingly unprofitable operation of coal mines. What he said is true, but he could have said more. He could have reported that never before has there been so much intense effort devoted to improving mechanical methods in coal mines as in 1924. Industry is bound eventually to profit by it in lower costs. In fact there are already instances where costs per ton have been reduced as much as 25c. Never has there been a year in which union labor has had so severe a lesson in the short-sightedness of its policy of obstructing cost-cutting machinery. Perhaps it may change this policy now.

It is true the coal operator has no big 1924 profits with which to develop cost-cutting machinery and methods; he is being driven to it, instead, by desperate fear of destitution. So, even before union miners' wages are reduced, the industry is working steadily toward lower cost fuel and is thus performing a duty to the nation without "taking it out of labor."

### A Union Man Says It at Last

DOWN in western Kentucky is Lonnie Jackson, for years a stalwart labor leader and, until now, president of District 23, United Mine Workers. Nobody ever successfully accused him of being anything short of a loyal fighter for unionism. So unionism has persisted in his own region—Muhlenberg County—while it was collapsing everywhere else in western Kentucky. One reason for this was that coal operators knew Lonnie Jackson to be fair, square and sane. They were willing to deal with such a man. And they are willing now. But unbending adherence to the Jacksonville agreement makes it impossible. Lonnie Jackson says:

"I do not believe in an organization taking the stand that there will be no backward step regardless of circumstances. I believe that facts and figures should be governing factors in fixing wage scales at all times. This is my conception of the trade union movement or collective bargaining. Labor organizations should demand what they are entitled to at a time when conditions are favorable and they should be willing to grant concessions when things are unfavorable and if any district is suffering on account of inequality it should be taken care of through wage negotiations."

Talk such as this is not pleasant in the ears of President John Lewis. It is too true. And it is not pleasant for him to hear Lonnie Jackson say flatly: "Day by day I have seen mines go non-union. I have seen non-union tonnage soar to an alarming extent. I have seen operators, who were always willing to sign contracts with the United Mine Workers, permit their mines to flood because they cannot sign an agreement that will not permit them to compete with non-union tonnage." Jackson knows that "it will be the duty of the officials of our organization as long as they work and receive pay therefor, to oppose what I am saying . . . but I am endeavoring to put before the miners and the public the facts as they appear to me. I am conscientious and I do not fear the result, whatever it may be." And there the case stands.

There isn't much for President Lewis to do or say in reply. He knows this man speaks the truth. But his own hands are tied effectively. He cannot advocate a reduced union wage in western Kentucky, because if he did he would be sacrificing his locals in Illinois and other competing fields—that is, unless he agreed also to a cut in Illinois and the whole domain of unionism. And if he did that right now he would be doing a futile thing. He probably would fail to get the reduced scale accepted and he certainly would succeed in getting himself rushed out of a job. Such is the psychology of the union miner. No "backward step" can be taken until the rank and file demands it, and that may not be until next summer. Till then, at least, conditions must remain *in statu quo*.

For the time being, everybody is right. Lonnie Jackson is right in advocating a cut, just as the Alberta union miners were right this month in accepting a reduction rather than be sacrificed by the international. President Lewis is right because union politics will not permit him to do what he knows should be done. So the confused situation must remain confused—while sections of union territory go non-union or reject headquarters control—until action is initiated by the rank and file. That action is a little closer because such men as Lonnie Jackson have begun telling the union the truth.

Coal Getters

## Is the Payroll Dollar Worth the Mine Dollar?

Many Executives Do Not Realize That Wages Are Invested  
— The Wage Dollar Should Pay Dividends — Human  
Engineering Is as Indispensible to Success as Mining Engineering

BY H. J. GROSSMAN  
Cleveland, Ohio

ONE OF THE principal sources of loss to the coal industry is the mistaken idea held by most executives that the "mine dollar" is greater than the "payroll dollar." In other words, a great many executives think that the money invested in their mines and equipment should be more carefully watched than that which is paid out to employees in the form of wages. Either they do not realize that the money spent in this way forms ultimately a far larger investment than that put into mine and equipment, or else they choose to ignore this fact. The result is waste which is passed on to the ultimate consumer in the form of increased mining costs and higher prices.

Not only do most executives fail to realize that investment in payroll—wages—is ultimately a much bigger investment than that in plant and equipment but they also fail to realize that it is fundamentally a more important investment as well. On the average, business cash invested in payroll will exceed cash invested in mine and equipment within two or three years. Even in the largest enterprises the former investment will exceed the latter within five years.

It is impossible to evade the fact that every wasteful practice in the mining of coal is translated into cost. This cost becomes a direct burden on the consumer in the form of higher prices, if a profit is to be made on the output of the mine.

In contributing to this waste and the resultant higher cost of production, some important factors are: the impurities loaded on the cars in the mine and

eventually shipped to the consumer, careless handling or rough treatment of tools and equipment, absenteeism and "idle days," restriction of production, opposition to labor-saving devices, uneconomic restrictions, strife and friction, and the like. Much of the waste complained of is due to the attitude of the executives toward their employees and of the employees toward their jobs. Perhaps a larger portion of it may be charged against the attitude of the executives than against the attitude of the employees, for it is upon the former that the latter largely depends. In other words, if executives insist upon giving 95 per cent of their attention to the mechanical side of the business and only 5 per cent to the human side, they have little to complain about if their employees give 5 per cent of their attention to their jobs and 95 per cent to their personal interests. Regardless of what percentage of attention the employees give to their jobs, however, it is obvious that sooner or later any inattention will be reflected in waste.

### CO-OPERATION IS THE ONLY ADEQUATE SOLUTION

The question of how wastes and the losses they produce may be lessened in a substantial way, if not prevented entirely, may be answered with a single word—co-operation. The task of obtaining co-operation, however, is by no means simple. Some employers have tried to obtain it by placing industrial spies in their plants to report delinquent employees, who are discharged; but they have failed. Other employers have striven for co-operation, their various activities being classified under the head of welfare work. They have tried to win the co-operation of their employees by giving them something; and they also have failed.

NOTE—Men, after all, are the greatest assets that a coal company can have. The headpiece shows a group of miners waiting at the shaft bottom to be hoisted to the surface. This is the raw material with which the human engineer in the mining industry has to work.

This naturally brings up the question as to how co-operation really can be obtained. In a negative way it may be answered by saying that it can rarely come from the inside of the organization, because the average executive is unable to analyze the motives that control his employees. To do this properly and effectively it is necessary to approach the matter from an "outside or detached" (not disinterested) viewpoint. The executive himself, being on the inside, the viewpoint is denied him. In a word, it is a case for the trained "man engineer."

Let us cite a case in point. In it figured a mine equipped with the most efficient machinery, labor-saving devices, plentifully equipped and engineered, yet unable to produce coal at a profit. A survey of conditions in the mine showed an antagonistic attitude on the part of the employees toward the management. This resulted in their opposing the purpose of the equipment and

Unnecessary driving tactics indulged in by those charged with supervision also materially adds to the mining cost through expensive labor turnover and increased antagonism from the workers. This feeling expends itself in opposition to the management's interests. Education of the foremen along similar lines, supplemented by a strongly applied constructive policy will eliminate these losses accruing from the supervision. It is all a case of determining motives and working up the spirit of co-operation through understanding.

#### CO-ORDINATION REDUCES PAYROLL LOSS

The annual payroll loss in some mines is almost unbelievable. In a large operation the payroll was found to be sustaining an annual loss of 25 per cent of the total wage disbursement. By developing a greater degree of co-ordination and constructively

#### Those Who Actually Produce Coal

Color makes little difference in loyalty. The important consideration in any industrial enterprise is morale. This may be intangible, incapable of measurement or appraisal, yet it is none the less highly important. The loyalty of even such men as these roof-brushers is well worth securing by the management of any mine.

labor-saving devices, thereby restricting production, and causing great losses and wastes. They had been educated by outsiders to believe that these practices were to their interest.

An intense educational effort in the simple economics of the situation, developed a comprehension of the fallacy of their previous methods and practices. This resulted in the economical and cleaner mining of coal, which permitted the operator to offer a price inducement and to extend his area of distribution, thereby providing more stable employment under more agreeable conditions for his workers. The secret was the "outside" or analytical viewpoint and the educational method practically applied. Thus success was achieved through enlisting the co-operation of the employees and their interest in their work to a point where they had a fair understanding of the identity of interest. The executives of this mine had been neglecting its greatest asset—the goodwill and understanding of their workmen.

molding the employees, as well as the foremen and contractors to the proper appreciation of their responsibility and to an understanding of simple economics, the greater part of this loss has been recovered.

That the minds of mine workers are not closed to developments of an economic nature is proven by an experience recently had in a non-union operation. Although the mine was operating more or less continuously under a reduced wage scale, the conditions of the coal market plainly indicated a curtailment of output. Realizing that a reduction in price would stimulate sales, and that they would be far better off working for a slight reduction five days a week than one or two days a week at a higher scale, the miners made their views known and graciously accepted the reduction in wage. No doubt when orders are again plentiful they will promptly receive a substantial increase from this constructively inclined operator.

In undertaking the reduction of mining losses, sight must not be lost of that fact that every working force

### Common Ground

First aid training in most cases has done far more than teach men how to apply bandages—it has taught them how to meet and appreciate each other. When employee and employer meet in a common cause, differences of opinion are apt to be forgotten. Nothing welds people together more firmly than to work for a common objective or to play on the same team.

is made up of three types of employees—conservative, radical and neutral. Analysis of mines and plants in more than 50 industries has shown that, in a group of 100 typical employees, 10 per cent are conservative, another 10 per cent are radical and the remaining 80 per cent are of neutral motive.

There is no loss on the payroll dollar of the first group, because the employees in it return a full day's work for the wages they receive. The radical-motive group will produce only 50 per cent of a full day's work, with a consequent loss of 50 per cent of the wage investment in them. The 80 employees in the neutral-motive group produce only 75 per cent of a full day's

work, and there is a loss of 25 per cent on their payroll dollar. The net result is, in this case, which is typical, a loss in productive value of 25 per cent of payroll investment per hundred employees.

Appreciation of science in machinery and mining engineering is essential in the coal industry but, unless the good-will of the employees can be obtained, no system will earn satisfactory dividends. The co-operation of the mine workers can be had by any employer who will meet them half way. The viewpoint of the employee is the most neglected factor in our modern mining industry. It deserves far greater consideration than it now receives.

### A Reliable Crusher Installation

At a certain mine in Illinois a ring crusher was installed about three years ago. This machine is driven by a 50-hp. motor and is used to reduce large coal to stoker size. Since its installation it has crushed a total of 240,000 tons of coal, some pieces being as large as 2 ft. chunks. On the average about 1,100 tons of fuel are passed through this machine each shift.

Thus far no repairs whatever have been necessary on this machine. Expense of operation, including interest, depreciation, etc., amounts to \$13.39 per day, which brings the cost of crushing to 1.2 cents per ton. Many coal mines during recent years have installed crushers so as to be able to supply stoker fuel to the trade whenever the demand for this grade is strong. The results obtained in this installation in Illinois show how reliable these crushers can be made.

The Ghost Car of the Rocky Mountain Region

The United States Fuel Co., with headquarters in Salt Lake City, Utah, operates the only white coal car in captivity—and only one. This car, which shines out like Little Eva among the Tops'es and the Simon Legrees of coal traffic, is used as an advertising feature for "King" coal. It makes trips here and there among the customers of the company, attracting attention wherever it goes. In this photograph, it stands in the load yard of the Blackhawk mine at Hlawatha, Utah.

# How Dangerous Ground Currents Were Prevented And Confidence of Workmen Regained\*

Stray Currents Were Eliminated from Shaft and Equipment by Interconnecting Cables—Leads on Firing Caps Should Be Short Circuited Until Used—Damaged Blasting Cables Must Be Replaced at Once

BY EMORY E. JONES

Electrical Engineer, E. E. White Coal Co., Statesbury, W. Va.

IN THE LATTER part of 1922 a shaft was sunk on the property of the E. E. White Coal Co., at Statesbury, W. Va., to the Pocahontas coal beds Nos. 3 and 4. When the shaft had been sunk to a depth of about 65 ft., a premature explosion occurred in the following manner: A sumping shot of eighty sticks of dynamite had been prepared and connections made to an electric blasting circuit of 250 volts direct-current located on the surface. Due to an open circuit in the blasting cable, which ran from the surface to the bottom of the shaft, the charge could not be made to detonate. As two men started to descend the shaft to locate the open circuit, so that the work could proceed, the charge of dynamite exploded. Fortunately, no one was injured, as the shot had been well placed and properly loaded, so that no rock was thrown to the surface.

It was now evident that conditions were extremely dangerous, and the cause of this premature explosion must be found and eliminated. The confidence of the workmen had been shaken and some of them refused to proceed with the work unless steam instead of electricity was used for hoisting and pumping purposes.

Because of the fact that all the equipment was electrically operated and the machinery for sinking had all been installed, it was practically out of the question to use steam. It was therefore evident that the cause of this explosion must be found and remedied.

It was known positively that the circuit leading to this charge of dynamite was open, and that the switch had been disconnected some time previous to the detonation of the charge. It was also believed that the shot had in some way been detonated by what is commonly known as a stray current.

## TESTS MADE TO DETERMINE EXACT CAUSE

A number of tests were made to determine the exact cause. In making these tests, first, all the switches were opened, and an ordinary electric blasting cap was connected between the compressed air line and the discharge line from the pumps located at the bottom of the shaft. The instant the connection was made the cap was fired. This showed that a sufficient difference of potential existed between these points to detonate an electric blasting cap. A connection was made between the air line going down the shaft and the ground adjacent thereto. Again the cap was fired, but not instantly, thus showing that there was not at all times sufficient voltage between these points to fire the cap. A connection was made between the electric hoist frame and the ground and the cap was fired instantly. A connection was made between the shaft bottom and a wet place near the surface and the cap was fired in a few seconds.

From these results it was evident that sufficient dif-

ference of potential existed between the places selected to fire blasting caps connected in an ordinary circuit in the shaft. To equalize the difference of potential existing at these various places, connections were made with heavy copper wire as follows: The frames of all the machines on the surface, and the pipe lines going down the shaft were electrically connected; holes were dug near the hoist and compressors, and ground connections were made by burying a coil of wire, and bolting the

Drilling a Hole by Hand

Whether the hole be drilled in rock or coal makes little difference—damp earthy materials form a conductor that may carry current of sufficient strength to set off a detonator. High-resistance joints in rails, gaskets in pipe lines and a hundred and one other things, not perceptible to the eye, may influence not only the magnitude of stray currents but their path as well.

connections to the frames of the machines; salt water was poured on these coils of wire to increase the conductivity, and earth packed over them to fill the holes and insure good contact with the ground.

Tests were then made with a millivoltmeter and no difference of potential greater than 100 millivolts could be detected between any two pipes, between a pipe and ground, or from the top of the shaft to the bottom of the shaft.

After these tests had been completed several blasting caps were given to the workmen, and a prize of \$25 in cash offered to anyone who could cause a cap to fire at any place except by the use of the blasting circuit. It was amusing to watch the efforts of the men to fire the caps, and the precautions used in case they should explode. Not being successful in their attempts it was noticed that some of the workmen believed that the caps handed to them were imperfect. They thought these caps to be "phoney." In order to dispel this suspicion each cap was connected to the blasting machine,

\*Paper presented before Mining Section of National Safety Council, Louisville, Ky., Oct. 2.

**Drilling a Shot Hole Electrically**

By what means a hole is drilled makes very little difference so far as stray currents are concerned as the real danger comes between the time of charging and the time of firing. Note, however, the rock band below this shot hole. It may have high resistance while the coal above and below it may have comparatively low resistance. Suppose that in inserting the cartridge and pushing it home one lead wire is scraped bare making contact with the coal and that the bare end of the other wire touches the damp floor. Then suppose that a stray current seeks passage from the coal to the floor. What will happen is obvious.

and fired, thus restoring the workmen's confidence, so that the work could proceed without fear.

The following rules were then posted regarding blasting, and rigid adherence enforced.

Rule 1. Explosives must be placed in an insulated container when being lowered down the shaft.

Rule 2. Not more two men may be in the shaft when shots are being prepared.

Rule 3. The muck bucket must not touch the bottom of the shaft during preparations for a blast.

Rule 4—The blasting machine must remain in the possession of the top man, and may be operated only by the man who prepared the shots, and then only in the presence of the top man.

Rule 5. The whole length of the shooting cable must be inspected daily. If a bare place is found, the cable must be thrown away and a new one secured.

There are obvious reasons for each of these rules. First, if the explosives are in an insulated container while being lowered down the shaft, there is no danger of an electrical contact being made. Second, if only two men are in the shaft during the preparation of the shot, it is certain that not more than two men could be hurt in the event of an accident. Third, if the muck bucket does not touch the bottom, there is no danger of stray currents radiating from it. Fourth, if the blasting machine is in charge of one man, one particular person is responsible for its safe keeping and if the man who prepares the shots is the only one allowed to use the machine, it is evident that no one will connect it until everyone is out of the shaft. Fifth, if a well-insulated blasting cable is used, and it comes in contact with any charged machines or pipe lines, the insulation will prevent leakage of current to the blasting cap.

Since the accident mentioned above some thought has been given the subject, and improvements made in the way of handling electric detonators, especially inside the mines. In the case of the E. E. White Coal Co. the miners are taught to twist the bare ends of the wires of the blasting caps together and keep them in this condition until they are finally connected to the

blasting circuit. This simply means that in case the wires of the cap come in contact with a source of current, the ends being short-circuited, there is no danger. Caps are always delivered to the men in paper sacks properly closed at the top so that the ends of the wires can not come in contact with any source of current. The men are taught to suspend blasting cables on wooden posts, and never allow them to come in contact with mine tracks. Blasting batteries are made in such a way that a connection to them cannot be made unless the cable is held in one hand and the battery in the other. Thus there is no danger of a workman leaving his battery connected to a cable and going to the face and attaching another cap. Accidents have happened where miners have left their cables connected to battery terminals and attached blasting caps at the charge.

To those who have studied electrolysis the subject of stray currents is a familiar one. Much study has been given this subject, and some electric railway companies have gone so far as not to use the rails or ground for return circuits at all, in fact, this is the case in Cincinnati. The danger here is not so much the premature explosion of shots but the electrolytic action on steel structures.

If an electric current is passed through a liquid from one metallic plate to another, electrolysis will take place; that is, metal will be deposited on the negative pole, and the positive pole will be dissolved. In an electric railway return circuit there is a difference of potential between parts of the system and the rails and other buried metals, such as pipe lines, steel structures, fire plugs, telephone cables and foundations of buildings. The amount of these differences of potential depends somewhat upon the energy loss in the return circuit, it varies with the amount of current flowing, and the resistance of the return circuit.

It is therefore evident that if pipe lines and buried pieces of metal are all connected together with low-resistance cables, these differences of potential may be practically eliminated. However, it is not so evident that different strata of earth are of relatively low resistance and sometimes separated by a stratum of comparatively high resistance. Nevertheless this accounts

**Loading a Hole**

When handled properly explosives are harmless: if handled improperly they "let go." The blaster must not only look carefully to the charge of powder itself but also to the detonator and its lead wires. Twisting the bare ends of these wires together forms an electrical connection between them and greatly lessens the danger of premature explosion. This process practically converts the leads from two separate wires into one continuous conductor with no opportunity for current to flow to the cap. Furthermore, joining the wires' ends keeps them together so that they are not likely to touch two points of appreciably different potential.

#### A Place to Begin to Control Currents

Unbonded or poorly bonded tracks are a continual source of danger and expense. Any current that leaves a generator must return by some circuit or another. If the rail joints present a high resistance the current will pass through the materials offering an easier path.

for differences of potential between earth strata. By the same token, where current is flowing through the earth, there are differences of potential between points on the surface, or between the surface and underground, depending upon the difference in their distances from the source of current the conductivity of the various strata of earth and the amount of current flowing. The first experiments in wireless depended upon this principle. When we consider the small amount of current necessary to fire an electric detonator, and the small amount of voltage required, it is evident that care must be taken not to allow the bare ends of the caps or bare places in the blasting cable to come in contact with conductors, especially pipe lines, steel rails, ponds of water, or wet places of relatively high conductivity due to mineral salts and acids.

It is strongly recommended that all electric blasting-cap wires be twisted together during the process of manufacture, thus minimizing dangers in the field should the wires accidentally come in contact with materials having a difference of potential between them.

The cables used for the purpose of electric blasting are usually poorly insulated and cheaply constructed. The insulation consists chiefly of cotton treated with paraffin. A great improvement could be made in this direction which would add to the safety of electric blasting. Manufacturers of electric batteries used for firing electric blasting caps can improve their construction by so arranging the batteries that no permanent connection can be made to them. This refers, of course, to the batteries used by coal miners, where only one cap is fired at a time.

For the benefit of those who wish to calculate the resistance of blasting circuits, I quote literally from J. H. Horlick, Jr., of the Hercules Powder Co., who very kindly furnished this information.

"The actual amount of current required to heat the bridge of our electric blasting cap sufficiently to set off the charge in the cap is approximately 0.4 amp. However, in actual blasting, and with more than one cap connected in the circuit, a greater current is recommended to take care of any slight variation in the bridges of the caps or of any leakage which may occur in the circuit, especially under damp conditions or in

metal-bearing materials. For various types of connections we therefore recommend the following currents:

1. For series connection, not less than 1.5 amp.
2. For straight parallel connections, not less than 0.6 amp. per cap in parallel.
3. For parallel-series connections where the caps are in series groups and the groups in parallel, not less than 2.0 amp. per series.
4. For series-parallel connections where the caps are in parallel in groups, and the groups in series, not less than 1.0 amp. per cap in the largest parallel group.

"Of course, it is quite possible to get satisfactory results with less currents than recommended above, especially when a number of caps are placed in the circuit. However, the above minimum currents are recommended so as to have some margin of power to take care of any irregularities in the circuit and provide greater assurance of all caps firing.

"With the necessary current determined, the required voltage then depends upon the resistance of the circuit. In this consideration it is important that the resistance of the entire circuit, and not that of the caps alone, be calculated. For instance, suppose we had a circuit consisting of ten 10-ft. No. 6 copper wire E.B. caps in series with 500 ft. of No. 14 copper wire to the source of power. The resistance of E.B. caps, of course, varies with the length and kind of leg wires, that of Hercules 10-ft. No. 6 copper wire E.B. cap being 1.50 ohms. Ten in series would therefore have a resistance of 15.0 ohms, while the 500-ft. of lead wire would have a resistance of 1.26 ohms. With the minimum recommended current of 1.5 amp. for this series circuit, the required voltage by Ohm's Law would be about 25 volts. For firing only a single cap, a current of only about 0.5 amp. would be sufficient to use in calculating the required voltage along the above lines, in which case about 1.5 volts would probably fire the 10-ft. copper wire cap. It is interesting to note that if a stray current should get through the cap wire insulation near the cap itself, thereby eliminating the leg wire resistance, a voltage as low as about 0.6 volt might fire the cap. However, for more than one cap in regular blasting circuits, we recommend calculations for required power based on more than merely theoretical required current, in order to more thoroughly insure the firing of all caps in the circuit."

#### Take No Chances With a Damaged Blasting Cable

Bare spots in a cable may touch a mine rail, charged conductor or a pipe carrying current and fire a charge. Inspect the cable every day and replace it with a new one if it is damaged.

# Equipment and Safety Methods in Alabama

Auxiliary Fan Drives Assure Reliable Ventilation—Rotary Dumps Discharge Whole Trip at One Operation—Mechanical Samplers Influence Coal Quality—Dust Laid by Washing Down Mine Surfaces

BY MILTON H. FIES

Vice-President, De Bardeleben Coal Corporation,  
Birmingham, Ala.

**V**ENTILATING furnaces are still in use generally at drift mines in Alabama where no power is available. This system is costly and inefficient. At practically all mines where power is available various types of fans are used. At some drift operations small fans of about 5,000 cu.ft. per minute capacity are employed; one machine furnishing air for one or two openings. At larger developments, where methane is generated, there are usually two drives to each fan. One of these is generally a motor and the auxiliary drive a steam, gasoline or kerosene engine.

At the No. 1 air shaft of the Woodward Iron Co. a No. 16 Sirocco fan has been installed. This is driven normally by a 150-hp. motor; the auxiliary unit consists of a 100-hp. Fairbanks-Morse kerosene engine. This engine is direct-connected to the fan shaft by a sliding jaw clutch. The motor is connected to the fan by a belt, the pulley being loose on the shaft but provided with jaws cast in the hub to engage a sliding clutch. In case of power failure, it is only necessary to throw out the clutch on the belt pulley, throw in the other clutch and start the engine.

The engine is started with compressed air from a receiver. This is always kept up to pressure by a small compressor that is driven by a 9-hp. gas engine. The entire change can be made in less than 5 minutes. Storage batteries are provided to furnish lights for the attendant at the fan in case of power failure. The layout of this auxiliary drive is shown in Fig. 23.

Both the continuous and split systems of ventilation are in use in the mines of Alabama. In the larger and better-equipped operations, the split system is prevalent. Concrete overcasts and stoppings made of mine rock, faced with a mixture of clay and cement, are found in the better-class mines.

## IN SOME MINES MUCH WATER MUST BE HANDLED

It has been found that as pillars are removed, particularly in the Warrior field, the cost of pumping increases greatly. In some of the Pratt mines, where pillars were robbed as the entries were driven to the boundary, from 10 to 15 tons of water have been pumped for each ton of coal produced. It is now the custom, at the larger operations, to extract not over 50 per cent of the coal as the mine advances, leaving large thick pillars. These are robbed as expeditiously as is practicable toward the end of the mine's life. The reduction in pumping by this method will be great.

In the Cahaba field, where all the beds pitch, pumping is a large item of expense, mainly because there are conglomerate and other porous strata above the coal measures. The drainage problem is simplified, however, by the ability to lead the water to a common point.

Methods employed in timbering vary greatly accord-

ing to the top, and no set principle is followed. The cost of timbering ranges from 1c. per ton to 7 or 8c., depending on the nature of the top and the accessibility of the timber. In recent years, the cost of timber has increased, through the exhaustion of the supply readily available. It is not uncommon at some mines to have the timber shipped in by rail or hauled 10 to 15 miles in trucks.

In the larger, better-equipped mines, slope and main haulage track is laid on sawed creosoted ties with 40 to 60-lb. steel. On cross entries, where mule haulage is used, the rail is 20 lb., but with locomotives it is 30 to 40 lb. Room rails vary from 12 to 20 lb. in weight.

In medium and steeply pitching beds, as a general rule, mules are used on all cross entries for gathering coal to the slopes. Where the pitch is from 0 to 5 deg. locomotives are employed almost entirely for gathering and main-line deliveries. Storage-battery and gasoline machines are used at a few operations and in a few cases endless and tail-rope haulage systems are found.

## BELT CONVEYOR USED AS A SLOPE HOIST

At one mine in Alabama, a belt is used for hoisting coal up a slope. This conveyor operates on a pitch of 19 deg. 53 min. The belt is 4 ft. wide, with troughing idlers on the upper and straight bearing idlers on the lower strand. Head and tail centers are 485 ft. apart and the belt is kept taut by passing over an idler pulley to which a counterweight is attached located just under the head pulley. The coal is discharged in a one-car revolving dump underground. Under this dump is a hopper, which holds about 6 tons, or the capacity of three mine cars. Beneath the hopper is placed a reciprocating feeder which feeds the coal from the hopper to the belt. This feeder is perforated and the slack coal goes to the belt first and the lump coal is deposited on top of it. The belt has a capacity of 2,500 tons per day of 8 hr. A 75-hp. motor drives this conveyor as well as the reciprocating feeder. The advantages of this system are reduced cost of all tippie and head-frame structures, a lower operating expense, a smaller investment in hoisting machines—a 75-hp. motor as against an expensive hoist of 500 to 700-hp. capacity. By regulating the feed at the bottom of the slope coal can be fed to the shaker screen in the tippie with such regularity as to make the screening highly effective, and all danger from slope trips is eliminated.

This belt has been in operation about a year and no wear is noticeable. The mine has not been brought to its full capacity, but 1,100 tons have been handled over this conveyor in one day with the belt standing idle about half of the time.

With beds of such diversified thickness and pitch as here prevail, many types of mine cars are in use in the state. In the more recent developments, cars with-

NOTE—Fourth and last installment of article entitled, "Alabama Coal-Mining Practices," presented at the Birmingham meeting of the American Institute of Mining and Metallurgical Engineers.

out end gates, and revolving dumps with which to discharge them, are becoming the general practice. At one operation, on a 25 to 35 deg. pitch, Griffith bottom-dump cars are being used with success. One type of tippie installed at a slope mine, and which well illustrates the use of revolving dumps and gateless mine cars, is shown in Fig. 24. This tippie handles about 2,000 tons per 8-hr. day with a counterbalanced haul of five cars per trip. The capacity of the cars is 3,500 lb., making about 9 tons of coal per hoist.

The coal is pulled from the loaded yard up a 30-deg. slope about 1,100 ft. long by an 800-hp. Vulcan hoist. The drums are 10 ft. in diameter with a 4-ft. 6-in. face. The rope speed is 1,800 ft. per minute. A 500-ton reinforced-concrete bin, located over two standard-gage railroad tracks, receives the coal from the gravity dump. The bin is 39 ft. high on the approach end and 49½ ft. high on the hoist end; this gives an angle of about 8½-

Fig. 23—Auxiliary Drive for a Mine Fan.

When the fan is down the mine is down. This layout shows a fan normally driven by belt from a motor. Should a mishap befall this motor or should the source of power fail a kerosene engine may be started and the fan driven by it. Both engine and belt pulley are clutched to the shaft so that shifting drives is a matter of only a few minutes.

deg. in the gravity dump, and facilitates the prompt return of cars by gravity after they have been discharged.

Hoist operation is controlled by electric signals from the man on the tippie, when cars are ready to be returned to the mine, and from the man in the loaded yard, when the trip is ready to be pulled out. The coal is weighed in the underground yard and pulled into the dump which is released by the operator on the tippie. The dump is rotated by the weight of the coal. As the cars empty, the dump returns to its normal position, and latches automatically. It is then ready for the next trip. As the coal leaves the cars in the dump, part of it is caught by sampling chutes in top of the bin.

Every precaution has been taken to make the tippie as fireproof and safe as possible, the main structure being of reinforced concrete and steel. At the top of the tippie, on the hoist end, a 20,000-gal. water-storage tank is provided for fire emergency.

#### INSTALLATION AND ADVANTAGES OF SAMPLERS

All mines in Alabama employ a dockage system whereby miners are penalized for loading excessive quantities of slate or rock. The method generally used to check up the miner is to pick a few cars at random, unload them carefully, a shovelful at a time, and inspect closely the entire contents of each car. The weak point in this method is that only a few cars can be inspected

during one day's operation and the miner, knowing this, will take the chance of not being discovered.

Erskine Ramsay, first vice-president and chief engineer of the Pratt Consolidated Coal Co., has perfected a mechanical sampler that has made possible the testing and inspection of a large number of mine cars without actually unloading their contents by hand. The Ramsay sampler has been used more extensively by the Woodward Iron Co. than by any other concern in this district. This company installed its first sampler in May, 1920, at Dolomite No. 1 mine. Since then, two additional machines have been installed at this operation, three have been installed at Dolomite No. 3, and four at the Mulga mine; this gives the Woodward company a total of ten samplers.

At Dolomite No. 1, the coal is hoisted in four-car trips and is dumped four cars at a time by means of two Ramsay, rotary, multiple, slope dumps installed in parallel. Messrs. Crockard and Best, of the Woodward company, made such changes in the usual design of these dumps (which are generally power driven) as to make them rotate by gravity. Installed under these rotary dumps are chutes having hoppers at the top. Beneath the right-hand dump there are two of these chutes by means of which the coal is directed to a sampler room, in which one sampler is installed. Beneath the left-hand rotary dump, there are four chutes leading to a sampler room on that side of the tippie, in which are installed two samplers, each being served by two chutes. The chutes have a hopper arrangement at the top for receiving the coal samples and are equipped with rotary gates operated by cables passing over sheaves and extending to a position convenient for the sampler operator. This man is thus enabled to draw the samples one at a time as required for convenient operation (see Fig. 25).

At the sampler, as installed by the Woodward company, the operator releases the sample from the chute onto a double-deck shaking screen 24x42 in. in size. This feeds slowly to a 24x38 in. picking table. The upper of the two shaking screens has 1-in. circular perforations and the bottom screen ½-in. perforations. The lump material that passes over the upper screen is hand picked. That from the lower deck is discharged onto the picking table through a small gate and is likewise picked. The fines passing through the lower screen go directly to the coal car and are not considered in the sampling. The removal of this material, however, facilitates the sampling operation and makes more careful and faster picking possible.

At Dolomite No. 3 mine, practically the same arrangement has been installed. Here the coal is discharged from the mine cars by two Ramsay rotary dumps in trips of five cars each, instead of four cars as at Dolomite No. 1. Chutes of the same design lead from beneath the coal dump to the sampler room in exactly the same manner as has been described and are equipped with gates so that the coal may pass directly to the sampler or, if desired, may be retarded to suit the convenience of the sampler operator.

#### CARRIERS SUBSTITUTED FOR SAMPLER CHUTES

At Mulga mine, four samplers have been installed. These are arranged in two rows back to back, but staggered so as to allow sufficient space for the attendants. This installation presented unusual difficulties because of the small space available for the equipment. The amount of head-room was so small that it was not pos-

sible to install gravity chutes; therefore, a small motor-driven carrier was designed to transfer samples from the receiving gates to any of the four machines. This carrier is a small bottom-dump car with wheels running between the flanges of parallel 10-in. channels. A tripper is set by the operator at any of the four machines and when the switch is thrown, the car runs down, strikes the tripper and automatically dumps, thence returning to the receiving gate. A single loading point is possible at this mine as cars are hoisted singly and discharged by a one-car rotary dump.

This battery of samplers is the latest installation made by the company and several small improvements have been effected in the design. The shape of the skirt plate along the picking table has been altered and both shaker and table have been lengthened. The width of the machine remains 24 in., but the shaker screen

weigh hopper is ready for a new sample. To facilitate weighing, dial scales are used with posts 6 ft. high, thus bringing the dial to the level of the operator's eye. These scales are provided with dials 13 in. in diameter which are graduated to read half pounds.

#### COST IS MODERATE BUT RESULTS ARE BIG

This detailed operation applies to the Dolomite No. 3 mine, where the average sample weighs about 70 lb. and requires approximately 7 minutes to pick. The samples are identified by means of the miner's check number, which is fastened to the bottom of the car and is noted by the tippelman and passed down to the sampling room by means of a speaking tube. The sampler operator keeps a record headed at the top "Coal Sampler Record." At the left, on the next line, is recorded the name of the coal mine and on the right-

Fig. 24—Tippel at the Dolomite No. 3 Mine of the Woodward Iron Co.

Cars are hauled up the slope in trips of five. In the tippel an entire trip enters and is discharged by a rotary dump set on such a slope that the empty trip will gravitate to the mine. The angle of the dump is  $8\frac{1}{2}$  deg. which assures prompt return movement of the empties.

is 48 in., and the picking table is 54 in. long. The method of actually picking the slate is the same at all installations; that is, the lump is first picked as it passes over the upper deck of the shaking screen to the picking table.

At the lower end of the picking table, there are two compartments; that intended for coal is adjacent to and immediately under the apron of the picking table while that for slate is just beyond the coal compartment. The operator lifts the slate by hand from the table and drops it into the farther compartment; in the mean time the coal gradually passes off the picking table into the near, or coal, compartment. After the slate is picked out, the operator hastens the movement of the coal by brushing it into the coal compartment with his hands.

As soon as the lump coal has been picked, the small gate retaining the material on the lower deck of the shaking screen is opened and it passes onto the picking table and is picked, the coal and slate being deposited in their proper compartments. When the sample has been completely picked, the total weight registered on the scale dial is noted. A gate at the bottom of the coal hopper is then opened, allowing the coal to discharge into the car after which the weight of rock is noted. The rock is then discharged, the gates closed, and the

hand side in the same line is the date. Beneath this, in parallel columns, is the following information: First column, check number; second column, total weight of sample; third column, weight of coal; fourth column, weight of impurities; fifth column, percentage of impurities.

#### INSTALLATION COST DEPENDS ON TIPPLE LAYOUT

The total cost of installing the sampler depends, of course, on the layout of the tippel and whether or not the coal can be dumped directly into a chute from the sampler or must be transported for some distance. The expense also depends on the cost of supports for the sampler and sampling room, and other considerations of like character which are governed by local conditions. An estimate of the actual cost of one coal sampler complete, built by the Woodward company in its Woodward shops, without considering the cost of chutes, sampler room, sampler supports, etc., was about \$300. It requires from 3 to  $5\frac{1}{2}$  hp. to operate a sampler.

The scale is supported independently from the sampler, as otherwise the vibration would make close reading impossible. The Woodward company has found that the speed of the eccentric shaft operating the shaker screen should be about 150 r.p.m., also that the throw of the eccentric should be about three inches.

Fig. 25—Ramsay Sampler at Dolomite No. 1

This machine permits quick accurate sampling of the coal contained in a mine car. It has been the means of greatly decreasing the amount of rock and refuse loaded, hoisted and passed through the preparation plants. It tends to keep rock in the gob where it belongs.

Figures furnished by the Woodward company show that the percentage of slate and other impurities in the coal prior to the installation of the first Ramsay sampler, as determined by washer loss, was approximately 20 per cent of the total quantity of material hoisted. Since the samplers have been in operation the percentage of impurities, as determined by the washer losses, has been about 10 per cent. The company believes there is no question but that the reduction, amounting to approximately one half, in the quantity of impurities has been due entirely to the sampler. It is not necessary to give actual figures as to dollars and cents saved. The total amount will be proportional to the total quantity of material hoisted; the company has the 10 per cent direct saving in addition to another highly important economy secured by eliminating the hauling, hoisting, and handling of impurities to the washers. Only one-half as much refuse now comes from the washers and is thrown away as was formerly the case. Not only is the cost of hoisting this material entirely eliminated, but also the wear and tear on the machinery and all of the other incidental items involved in the useless and unnecessary operation of loading rock and impurities when the fundamental aim should be the mining of clean coal.

#### PROGRESS MADE IN MINING COAL SAFELY

Considerable progress is being made toward mining coal safely in Alabama. Progress made in this direction is best visualized by comparing records for a 10-year period, say 1913 to 1923. In 1913, 73.7 per cent of all coal mined in the state was produced by pick and shovel methods and only 26.3 per cent by undercutting with mining machines. During this same year, 68 per cent of the coal was produced with permissible explosives and 32 per cent with black blasting powder. In the year 1923, 53.8 per cent of the state's output was mined by pick and shovel methods, whereas 46.2 per cent of the production was derived from undercutting with mining machines. During the latter year, 78 per cent of the explosives used in coal mines were of the

permissible type and only 22 per cent was black blasting powder.

In brief, for the 10-year period, there has been approximately a 20 per cent decrease in pick and shovel mining and a corresponding 20 per cent increase in mining coal with machines. Permissible explosives show an increase of 10 per cent for this period, while black powder showed a decrease of 10 per cent.

Marked improvement has been made in the matter of laying coal dust in the mines of the state. The principal method now used is by the installation of pipe-line watering systems. In most of the large producing mines, efficient watering systems have been installed; while in some of the smaller operations, watering is done in a desultory way by the use of water cars. However, a considerable number of small operations do not use any means of laying coal dust in order to prevent its being raised into clouds with possible ignition and explosion propagation.

#### MINE SURFACES WASHED DOWN WITH GARDEN HOSE

In large producing mines, sprinklers are employed to wash down the coal dust on ribs, roof, and along roadways, using 50 to 100 ft. lengths of hose of the garden type. These methods have been supplemented, in a large number of operations by spraying water onto the cutterbars of mining machines to wet the coal dust during the process of undercutting. It can be safely stated that fully 90 per cent of the dust formed in Alabama mines comes from the face, and it has only been in the last two years that attention has been concentrated upon laying such dust at its source.

Where coal is undercut with mining machines, without the use of water at the cutter head, large clouds of dust are raised in the air. Furthermore, while the machine cuttings (bug dust) are being hauled, considerable leakage occurs through the cracks in the car bodies thereby increasing the quantity of dust along roadways. Since the introduction of water at the cutter chains, practically no dust is raised during the process of undercutting and the spillage and leakage of coal along roadways has been reduced to a minimum. In fact so great has been this reduction that there has been a considerable decrease in the number of road cleaners employed as compared to the number necessary before the introduction of water at the cutterbar.

The sprinkler systems installed in some of the mines of Alabama are among the best and most thorough in the United States. Pipe lines from tanks are laid from the surface or are connected with the discharge of pumps. Water is then carried to the face of all working places, where sprinkling is performed by men employed especially for this purpose. Fig. 26 shows the method of sprinkling in one of the mines and illustrates the care with which the coal faces are washed down.

From experiments performed at the mines, it was found that twenty-one times as much dust is raised at the face while coal is being undercut with machines as is raised by trips traveling at various speeds along the haulageway. It was ascertained further that five times as much dust is raised at the face while miners are loading coal as is raised by moving trips.

At shaft bottoms, under former methods, great clouds of dust were raised during dumping operations. Since dust has been attacked at the face, however, practically no visible quantity of it is thrown into the air during car discharge operations underground. The most strik-

ing change, however, has taken place in tipples on the surface. Under former conditions, tipples were enveloped during the greater part of the shift in large clouds of coal dust, but at present, the atmosphere surrounding them is clear.

#### SPRINKLING SYSTEMS HAVE AVERTED EXPLOSIONS

The cost of maintaining efficient sprinkling systems in Alabama is quite variable, depending on the output. It ranges from a few cents to 6c. per ton. Such a system, of course, is quite expensive to maintain, but it can be safely stated that, in the past few years, explosions originating in the interior of certain mines have been prevented from propagating throughout the workings by the efficient system of sprinkling employed.

Considerable interest is being manifested in this district at present in the use of rock dust as an explosion preventive. Insurance carriers, as well as the Federal government, have been active in the promotion of rock dusting in this state. It is only a matter of a short time until even the most efficient methods of explosion prevention by the use of water will be supplanted by the use of rock dust.

In addition to the strides that have been made by reason of the introduction of permissible explosives supplanting black blasting powder, the substitution of mining machines for solid shooting methods, and the use of water for laying coal dust, together with the interest manifested in the use of rock dust, some of the mines have, within the past few years, introduced permissible electric cap lamps. The progress in this direction has been rather slow, but it is only a matter of a short time until a more extensive use of closed lights will be adopted, especially in the gaseous mines.

Since the Bureau of Mines established a rescue station in the Birmingham district, several thousand miners have been trained in first-aid and rescue work throughout the state. It is now quite rare to find a mine that does not employ a large number of men trained in first-aid and safety methods and in the use and care of breathing apparatus. These courses of instruction have done much to educate the miner in safety practices. Some of the larger operations in the district have been carrying on the training of their employees in first-aid and rescue work from their own central rescue stations. The Mining Department of the University of Alabama has provided a course in mining

for mine foremen and the more ambitious men about the coal operations are availing themselves of this opportunity. This course covers from four to six weeks, and the charge, including board, is nominal.

In some mines throughout the state, mainly as a safety measure, section foremen are employed. These operations are divided into sections of several entries each. Each section has a foreman, who superintends the timbering, the handling of explosives, and other safety measures, as well as the production of coal. Where this system has been adopted, accidents have been greatly reduced.

In the employment of labor, some mines follow what is known as a contract system. By this arrangement the contractor is paid a margin above the digging price, and acts in the capacity of a section foreman.

In Alabama, as in other states, the more progressive and humane operators add to their cost per ton by utilizing precautionary measures, while the less progressive operators sometimes disregard ordinary safety standards. As a result, during periods of fierce competition the progressive operators are at a disadvantage. While the principle of "less government in business" is, as a rule, sound, at the same time it must be conceded that a certain degree of government supervision is necessary when human life is at stake. The only means by which safety standards, applicable to all producers of coal, can be fixed, is through the action of the Federal government.

#### EXCELLENT MORALE PERVADES MINE LABOR

Alabama has made its own mine labor, which consists chiefly of native whites and negroes in the approximate proportion of half and half. There are some operations where 75 per cent or more of the employees are negroes. The state has been non-union since 1908. There have been two invasions by the United Mine Workers of America—in 1917, and a final effort in 1920 and 1921. The union failed in its efforts to organize the state because of the loyalty of the miners. It has been found that the best class of both whites and negroes have no desire to unite in the same organization; this feeling is deep rooted and sincere.

The operators of mines in Alabama are not unmindful of the fact that under non-union operation there is added responsibility on their part that cannot be shirked. In the last 10 years, conscience has been awakened to a sense of the duty that all men bear each to the other but more particularly the relation of the employer toward the employee. In addition, the white man is beginning to appreciate the value of the negro and to realize that after all each race has a common purpose and, in their respective spheres, should work for the good of all. In the main, the old argument, so often advanced by union organizers, namely, "absentee ownership" does not apply to Alabama, where many mine owners either live at their mines or visit them at regular and frequent intervals. Close acquaintanceship, which means common sympathies and mutual aims, is, after all, the basis for the best and most lasting relationship of man to man.

In the preparation of this paper, I am indebted to J. J. Forbes, District Mining Engineer, Bureau of Mines, Birmingham; C. H. Nesbitt, Chief Mining Inspector, also of Birmingham; J. L. Davidson, Secretary of the Alabama Mining Institute, and to the operating officials of many of the coal mining companies of the state for their assistance.

Fig. 26—Washing Down Ribs, Floor and Roof

In order to keep down the coal dust in Alabama mines not only is the cutterbar of the mining machine sprayed but the mine surfaces are washed with a hose as here shown. Dust is a dangerous enemy to mine safety.

# Mine Engineers Inspect Big Progress in Southland

American Institute Men Touring Appalachians See O'Toole's 50-Ft. Cutter and Loader, Jones' Big Loading Machine and Other Coal Mine Developments — Trip Through Many Fields Ends in Alabama Meeting

BY R. DAWSON HALL  
Engineering Editor, *Coal Age*

IN A SPECIAL train of six cars, four of which were sleepers, the American Institute of Mining and Metallurgical Engineers made a visit to the mines of the southern Appalachian region, starting from Washington, D. C., Oct. 7, holding sessions here and there and winding up in Alabama ten days later. They skipped the rich coal fields of Kentucky and Tennessee but visited those of the Pocahontas region, the zinc and copper mines of eastern Tennessee and the iron and coal mines of Alabama. By annual tours such as these, the members qualify themselves to take a broader view of the problems of their profession.

In the early days of the tour, while they were guests of the Southern Appalachian Coal Operators' Association, they had an opportunity to see the coal dry-cleaning plant at McComas, W. Va., the Jim Elwood Jones "Coloder," a big capacity machine combining scraper and conveyor, and Gen. Edward O'Toole's immense cutting and loading machine operating a 50-ft. cutterbar and drag scraper. They saw other interesting coal mining developments en route, and the coal men in the party learned a good deal in copper and iron mines which might be of profit to the coal industry. The trip, of course, included dinners and sight-seeing stops, as this annual tour always does, closing with a visit to Muscle Shoals.

## A BLOW AT OUR TAXERS

Col. Arthur S. Dwight, in his speech at the Washington dinner of the institute Oct. 7, declared that the city of New York might have the wealth of the country in its charge but that Washington has discovered a way for relieving it of that wealth to such a degree that it seemed as if Washington one day might become the rich and New York the poor city of the commonwealth.

Herbert Hoover, Secretary of Commerce, said that though large taxation was necessarily imposed, he supposed no engineer would take exception to \$65,000,000 annually which was expended in original research work, a sum equal to only  $2\frac{1}{2}$  per cent of the entire expenditure of the government. Part of this expense was due to the necessary regulative action of government. It is, he said, the only part of the government's expenditures that is reproductive. It returns its cost a thousand fold in reduced taxation.

Mr. Hoover declared that we could profitably double our expenditures for research. Unfortunately, we give our scientific staffs inadequate compensation. The highest salary paid is \$7,500 a year and that is given to scientists whose work is more largely administrative than scientific. The salary paid is rarely over \$5,000 a year and the average is but \$2,900.

Recently the government (U. S. Bureau of Standards) was prosecuting an inquiry into the ignition of gasoline in co-operation with an automobile association. An explosion occurred killing several of the experi-

menters. Twenty-two persons were deprived of their means of support by that accident but under the regulations the government could pay them an aggregate of only \$930 a year and had to look to outside organizations to supplement this meager compensation fund.

Mr. Hoover declared that all this was wrong, that men should not be asked to make such sacrifices on behalf of the government. They were entitled to pay commensurate with their talents.

## PUBLIC LIFE NEEDS MORE ENGINEERS

A tribute was then paid to the engineer by Mr. Hoover. "The engineer," said he, "is a servant of the truth. He is not swayed by his emotions but solely by facts, by truth. His interest is in physical forces and quantities. He believes in what he can prove and not in what he merely would like to prove. His is the guardianship of the fact. We should have more such men in public life. The engineer need not enter the national employ to help in rendering such service. He can, in his capacity as citizen, use his talent for reasoning on facts and thus aid in directing the policies of the nation."

The effect of emotion on politics was greatly deplored by Mr. Hoover. Recently, said he, he desired his secretary to find the facts on which the government ownership advocates based their arguments. The only tangible fact on which they relied was that at the Niagara Falls bridge the lights on the Canadian side with government ownership cost one-third as much as those on the United States' side with private plants. On this one fact was based the argument for an investment of 40 billions of dollars and the employment by the federal government of three million men. The question of ownership, whether public or private should not rest on opinion but on well-weighed facts.

## MINING KEEPS RAILROADS BUSY

Mr. Dwight remarked that 54 per cent of the tonnage on American railroads consisted of mineral products and 30 per cent of the revenue derived from transportation came from the carriage of these products. The importance of the industry, even during the present depression, made its unfavorable condition a matter of national concern, especially as it had resulted in the idleness of many capable mining engineers for the activities of whom the institute was trying to discover a new outlet. Among the other speakers were George S. Rice and President William Kelly.

That evening the visitors, about 72 in number, left for Luray cavern near Roanoke, Va. The cavern is a grotto or series of irregular passages, the result of solution and erosion in Silurian limestones and clays. The cavern has deepened with time. From the roof hang stalactites which look singularly menacing to a coal-mine man. Fortunately when struck they give out a pure and not a drummy note, so to all appearance

**"The Chapel" in the Grottoes of the Shenandoah**

In this grotto not only stalactites and stalagmites excite the wonder of the beholder, but natural rock much like the flies in a theater hang down over the fairy scene giving a most unusual effect. On the left can be seen a shield like a canopy and draped below with stalactites, standing almost without visible means of support. It is not as much inclined as many others.

they are not likely to fall, at least for some years.

In the Grottoes of the Shenandoah, visited by the party in the afternoon, the measures are vertical or nearly so in contrast to those at Luray which are almost horizontal. The appearance was therefore like the scenery in a theater stage as seen from under instead of behind the scenes. There, strange "shields" (probably of siliceous matter) had to all appearance partly fallen from the roof and become supported at varying angles on the bottom. They had then become cemented to the roof by the deposition of mineralized waters. In time the bottom of the cavern on which they fell was dissolved away and the shield can now be seen supported by the roof at one tip at what seems an impossible angle.

#### NO FIREBOSS WOULD PERMIT THIS

The rock thus suspended may weigh several tons. Ajax shield is 50 ft. above the floor; others are lower. The fire boss would certainly mark "Danger" against the area where the shield appears, yet mysteriously it is most firmly supported at its upper tip at an angle of 45 deg. to the vertical.

As the caverns are near the surface, nowhere much more than 200 ft. below the grass roots and as there is no oxidation to keep them warm the temperature is about 54 deg. the year round. The owner at Luray has taken due advantage of this fact and is ventilating his house with the pure temperate air of the cavern. He has adopted this means of keeping an even temperature in his house the year round. Before many years we also may be striving to get a similar result by artificial refrigeration and the use of fans though at a somewhat greater expense than that which the owner of the Luray cavern is incurring.

The morning of Thursday found the party at Bluefield ready for an early start. Most of the technical men visited the mine of the American Coal Co. of Alleghany County, at McComas, W. Va., to see the dry-cleaning plant. The coal at the mine comes out in lumps as large as any in the Pocahontas region, but the loading of the coal produces an immense quantity of dust even though care is taken to make the drop a minimum. The dust is so thick that the mine inspector has forbidden smoking on the tippie.

#### LESS DUST IN DRY CLEANING NOW

In the rescreening plant, which has been described at length in a previous issue of this journal, the dust is distinctly less in evidence. Unfortunately a little dust escapes and lodges on the floors and structural steel rafters. It is of course the finest of the dust. Should it become dislodged it might be sufficient to cause a small flare-up and explosion which might in turn dislodge more dust. On the whole, however, the impression gained is that the dry-cleaning plant is freer of hazards than the ordinary tippie, and the use of electric lamps tends to reduce the risk to a minimum.

Some of the finer dust, which would make excellent foundry facings, is escaping from the collectors and passing into the air almost like smoke. By use of the Cottrell system it might be saved, but the cost would be large, and the sale of foundry-facing material seems so limited as not to encourage a heavy investment in its collection.

Leaving the plant a visit was made to the Pocahontas Fuel Co.'s Delta mine at Switchback, which the members entered by a convenient opening at Maybeury. Here they saw the J. Elwood Jones machine, the "Coloder," at work in a short room 18 ft. wide. The machine is 6 ft. wide in front. The coal is crowded onto a drag scraper and is transferred to a conveyor and back to the car. With three placements of the machine the whole face is cleaned up.

Conditions are favorable in Delta mine. The coal is about 7 or 8 ft. thick; it is clean, and has a splendid roof and good floor. Cars have to be spotted one at a time behind the machine and for this reason its output is reduced.

Lunch was served at the Club House at Gary, W. Va., with Gen. Edward O'Toole as host. The party had

**Entrance to Baby Mine, Pocahontas Fuel Co.**

The visitors had a good chance to see the intensive development and the excellent roads between Bluefield and Gary. This is one of the many mines clustered in McDowell, Mercer, Wyoming and Tazewell counties and located in the justly celebrated Pocahontas coal field. It is located in the village of Pocahontas, Va.

swelled to several hundred. The visitors traveled about two miles to the No. 6 mine at Ream to see the O'Toole machine which is now working on a room pillar. The room is perhaps 25 ft. wide, and the rib being drawn is a little under 50 ft. in width. A cutterbar 50 ft. long undercuts the face of the pillar, which, being under considerable weight, tends to fall as fast as it is undercut.

Men with picks, however, are stationed along the face to bring the coal down should it fail to fall. It drops onto a drag scraper which carries it to the room roadway elevating it above the cars which stand in a trip at the loading point. A change has been made in the jacks used in moving the machine forward. One-hundred ton hydraulic jacks hold up the roof at the working face. It is probable that these will be replaced later by jacks of 150-ton capacity. The screw jacks which move the cutter and the conveyor forward each press against the base of a hydraulic jack and are operated by the driving mechanism of the cutting and loading machine.

#### HOW O'TOOLE'S MACHINE ADVANCES

The movement forward is automatic. However, the mechanism is so arranged that any screw jack can at pleasure be thrown out of operation. This is done whenever the hydraulic jack is to be moved up. The jack screws are 8 ft. long and advance the cutter and conveyor a distance of 6 ft. By moving forward one hydraulic jack at a time the cutterbar and conveyor need not at any time be stopped. The forward movement is continuous. There are always jacks enough in operation to move the machine ahead.

The bits drag the cuttings toward the edge of the pillar adjacent to the room track and here this fine coal is shoveled by hand onto the drag scraper. In order to support the roadway so that a trip can be stationed with its hindmost car well back in the goaf, heavy posts 18 in. to 2 ft. in diameter are placed along the track. The hydraulic jacks are provided with blocking on top, which can be rapidly and easily removed as soon as the water pressure on any one jack is relieved.

Some of the visitors went to the pulverized-coal plant at Gary. The Gary power station is using for fuel the waste from the picking tables, the railroad and mine-road cleanings. The material used runs from 25 to 50 per cent ash. The coal is pulverized in two Fuller-Lehigh mills so that 90 per cent goes through a 200-mesh screen. Practically all the power needed is

Tipple and Sizing Plant, Pocahontas Fuel Co.

For a low-volatile coal region, Pocahontas has coal that with proper treatment gives unusual opportunity for sizing. It makes a bad dust and when dumped into barges at the coast gets badly broken, but with care it will make a fair proportion of lumpy fuel well suited to open grates or the usual house furnace.

generated in two 800-hp. boilers which are run at 200 to 250 per cent of rating.

The coal is fed at the top of the combustion chamber with just enough air to carry it to the burners at the required velocity. There it burns, supplied with air introduced through openings in the combustion chamber. The fine ash falls to the bottom and remains a dust so long as it is not permitted to pile up high enough to reach the zone of intense heat.

#### NEW USE FOR BOILER-ROOM ASH

Vitus Klier, the chemist, is experimenting on the use of the "sand" which is the result of this intense combustion for the making of road and sidewalk surfacing material. When the ash is at such a temperature that it will not fuse and yet will effectually melt road tar, it will be mixed with that material, the whole being spread and rolled to an even surface.

The committee of the Pocahontas Coal Operators' Association which was entertaining the engineers, distributed an interesting little book containing the itinerary, a description of the region and a folding map, also an insert relative to the electrification of the Norfolk & Western R.R.

Friday morning, Oct. 10, the Institute train arrived at Mascot, Tenn., and one of the American Zinc Co.'s mines was visited. At this operation some of the openings were about 120 ft. deep, approximately 200 ft. long and over 100 ft. wide. The size of these mammoth stopes demonstrates quite clearly the strength of the roof in this mine. The roof cannot be tested as in coal mines but accidents in connection with it are rare. Unfortunately coal mines are not provided with a dolomite roof. If they were, accidents from falls would be far less frequent.

#### A TIP FOR COAL-COMPANY FARMERS

The company has an experimental farm which is kept in good condition by the use of the pulverized dolomite from its zinc mill. The corporation lays great stress on this agricultural effort setting thereby a good example to some coal companies which let their farms run down till their product will no longer pay the taxes. The American Zinc Co.'s farm is a good advertisement for its dolomitic product. Though the coal operator has no byproduct of this kind to sell there is no reason why he should prove himself the least thrifty farmer in the vicinity in which he operates. A large concrete culvert at Mascot prevents creek water from entering the mine and flooding the workings.

In the afternoon visits were made to the quarries of the Appalachian Marble Co., and the Gray Knox Marble Co., also the mill of the Knoxville Marble Co. Here the marble was squared, polished and in some cases reduced to slabs. In the evening the visitors were entertained at the Whittle Springs Hotel, about five miles from Knoxville, both a dinner and a dance being provided. Philip N. Moore's thoughtful speech on that occasion portrayed the new view of the engineer as to what are the essential elements in preparing for the practice of his profession. He believed that the engineer should have a broad education that would teach him not only the technical facts of his vocation but something of the arts by which the mental horizon of man was broadened. He questioned whether specialized technical ability could be acquired at college.

"When," said he, "we arrive at the ideal, an engineer

At the Mines of the American Zinc Co.

Photography only with great difficulty could be employed to convey the profundities of the artificial caverns at Mascot, Tenn. The roadways, often in the hanging wall or the footwall which are barren rock, are apt to be much like those in coal mining as is the one shown here, but in the stopes from which the ore has been drawn, the flood-lights provided for the occasion, only inadequately conveyed to the visitors the tremendous outlines of the enveloping pillars and roofs, and merely gave a rough sense of the immensity of their gigantic proportions.

will not be hired as a porter to do a special job at the behest of someone less able to do it but he will himself be manager and director, with the forces of the company that engages him wholly under his command. Today the lawyer and the banker direct, and the engineer fetches and carries for them."

In the early morning of Oct. 11 the train left for Ducktown, Tenn., arriving in time for lunch. In the afternoon the party went down the McPherson shaft and returned by way of the Burra Burra shaft, of the Tennessee Copper Co. At this mine and in other metal mines the compressed air pipes are kept above the floor, resting either on old drill shanks or on iron rods that are bent around them so as to embrace the pipe. All the chutes are closed by radial steel gates which cut off the movement of the ore by an upward motion. This is more certain than one that is downward, because in this instance the gate movement cannot be stopped by the flow of ore. The gate is moved by two racks and pinions, the pinions being near either end of a shaft rotated by a hand crank.

#### THIS CLOCK MIGHT SERVE A COAL MINE

At each shaft is a "clock" showing the number of lost-time accidents that have occurred during the current month, there being twelve points on the dial. The legend runs: "When a man is injured the hand moves. Can we go a month without moving the hands? This clock shows the number of lost-time accidents at this mine during the month. Below is a statement of the lost-time accidents for every month during the current year."

These three practices might be imitated with advantage by coal-mine companies. The metal mines, piped for compressed air, are not particularly wet, but the water may be unusually severe on pipe owing to its corrosive action. Coal-mine chutes are usually so planned that the gates close downward, not upward. In consequence they have to crush the coal if they are to be closed. In some cases they may choke and fail to stop the flow of coal. The upward-moving gate on the other hand, if it strikes a big chunk merely lifts it up by its end and proceeds to shut off the flow of ore in a positive manner and not merely by a choking of

the current. The clock method of dealing with lost-time accidents might be adapted to any mine.

Later in the day inspections were made by the engineers of the smelter and acid plant. In years gone by after the fumes from ore roasting had destroyed the grass over several square miles of territory and the floods had carved the unprotected ground into a badly gullied area and swept away the soil that had been accumulating for centuries, the company was compelled by North Carolina and Georgia to put in an acid plant. As a result 1,200 tons of 60- and 66-deg. sulphuric acid are now made per day.

#### IS THERE MONEY IN MINE WATER?

The production of copper is unprofitable at present prices, but the sale of the acid brings in an appreciable return. It would be at least worth while for coal companies to make further experiments to ascertain whether it would be possible to treat the waters from their mines so as to produce a not unprofitable by-product therefrom and so protect the creeks into which water from the mines is being discharged.

In the evening of Saturday, Oct. 11, the train went on to Chickamauga, and Sunday was pleasantly spent viewing the various battlefields in the vicinity.

At noon, the institute members were entertained at the Whittle Springs Hotel, on Signal Mountain, Col. William S. Shields, president of the Knoxville City National Bank being toastmaster. Addresses were made by Frank Bane, director of the Knoxville department of public welfare; William Kelly, president of the institute; Dr. Harcourt A. Morgan, president of the University of Tennessee; P. N. Moore, construction engineer and geologist, of St. Louis, and Wilbur Nelson, state geologist. The secretary of Knoxville Automobile Club delighted the audience by some well-rendered songs and a characterization of a negro pastor.

In the evening the special train moved on to Birmingham, where a technical session was held on Monday morning, conducted by George Gordon Crawford, president, Tennessee Coal, Iron & R.R. Co., chairman of the committee of arrangements. After an acknowledgment by Mr. Kelly of the welcome tendered by Mr. Crawford, H. S. Geismer briefed his paper on "Coal-Washing Practice in Alabama." In the discussion that followed Mr. Geismer said that three operators producing coal for the market had introduced coal-washing tables but that none of the companies producing iron were using tables for the cleaning of their fine coal. Frank H. Crockard, president, Woodward Iron Co., elicited the fact that at one point six mines were operating and seven washers, yet, in the reservoir below, gold fish had established themselves and had thrived so well that they had become an actual nuisance. Erskine Ramsay, chief engineer, Pratt Consolidated Coal Co., said that the water used in washing was saved, even that draining off the cars below the tipples being put back through the washer. Mr. Fies said that the mine water was probably acid, but that he had been surprised to find that the sludge water in the washery was alkaline.

F. W. Miller, manager, byproduct division, Sloss-Sheffield Steel & Iron Co., made brief remarks regarding his paper on "Byproduct Coking in Alabama." Theodore Swann, president, Federal Phosphorus Co., spoke on the value of phosphoric acid in the fixation of ammonia, declaring that it combined as satisfactorily with ammonia as sulphuric acid and made a more valuable fertilizer. It created more heat in the reaction but

not enough to occasion any difficulty. A product containing 60.5 per cent of phosphoric acid and 14.5 per cent of ammonia was obtained.

Milton H. Fies, vice-president, De Bardeleben Coal Corporation, then gave a brief outline of his paper on "Alabama Coal-Mining Practices," laying emphasis on the precautions being put in force in Alabama and regretting that, owing to local conditions, the record was not as good as in some other states. He said he had been much criticized for his advocacy in his paper of Federal legislation for the protection of mine workers. L. E. Bryant, of Tennessee, remarked that one mine was spending 15c. per ton of coal solely with the

**Mascot Mine of American Zinc Co. near Knoxville**

Part of the tailings from the jigs are used for commercial purposes, such as road and railroad ballast. Some of the jig tailings and all the flotation tailings are crushed and used for fertilizing purposes and as paint filler.

idea of promoting safety and added later that one of the Belgian experts who had been invited over by this government had remarked to him that safety provisions in Europe had doubled the labor cost of producing coal, bankrupted many of the companies in Germany, France and Belgium and caused the formation of syndicates for the purpose of sustaining prices at a level which would make such elaborate safety provisions feasible.

In this connection R. D. Hall remarked that in many cases the laws in one state were so much more severe than in another with which it had to compete that a desire arose for a greater uniformity of safety practice such as a Federal law would maintain. However, there were not many who wished the Government to undertake this regulation, which under the Constitution as now written would be without warrant. R. V. Norris said that the present state laws were not inadequate and were well suited to state conditions. He believed that safe production was cheap production and that a Federal law covering mines in all states was not desired nor desirable.

George S. Rice said that joint action between the states without Federal action was preferable. Uniformity of the laws was an end to be sought and it was to be hoped that it might be attained under Federal initiative. He said the recent laws passed in Great Britain had improved her accident rate and that better laws in the United States might have a similar effect.

The Federal government regulated, through the U. S. Bureau of Mines, the operation of mines leased from the nation. From these mines about 2,000,000 tons were produced annually. It must be remembered, however, that the accident rate was normally high in such mines because it chanced that the beds thus operated pitched heavily, increasing the natural hazard. In reference to Mr. Feis' statement that "It is only the matter of a short time until even our most efficient methods of water prevention will be supplanted by the use of rock dust as an explosion preventive," Mr. Rice said that in Great Britain rockdusting is required everywhere in bituminous coal mines whether naturally

wet or dry. Central France has not yet arrived at rockdusting, Germany is coming to it rapidly both in the Ruhr district and in Silesia, after a long period of firm faith in the value of water. Other mining regions of Europe are warm advocates of the value of rockdusting.

W. K. Kavanaugh, president, Southern Coal, Coke & Mining Co., of St. Louis, said that he believed that the state laws were in the main satisfactory and did not establish any unfair production-cost differentials between states.

The afternoon session concerned itself solely with metallurgical problems and the evening with geology and the working of iron ore. W. R. Crane, superintendent, Southern Experiment Station, U. S. Bureau of Mines, Birmingham-Tuscaloosa, Ala., showed wonderful slides exhibiting the methods of working the red iron ore and the effect of crush on mine pillars.

In between the afternoon and evening sessions a visit was made to the Shannon red iron ore mine of the Gulf States Steel Co., where a slope inclined at 52 deg. goes down 2,400 ft. to the iron-ore bed 1,900 ft. below the surface. There is little difference between a coal mine and any one of the many red iron ore mines of the Birmingham district, this Shannon mine, it is said, simulating a coal mine by having in its atmosphere a small quantity of methane.

The rooms are driven as in coal mining, leaving about 51 per cent in pillars. The work is unusual for this district in that the advance is in the lower 8-ft. bench, which is usually too siliceous for the profitable manufacture of iron. When a room has gone its due length the upper 12 ft. of ore is removed and the roof allowed to fall in on the retreat. The iron ore in the pillars is left. The roof is of shale and needs careful watching, and the bottom at times will heave, if overloaded. The inclined shaft, or slope, was driven by another company and without timbering. It fell in when about 20 ft. from the ore and had to be heavily concreted for its entire length.

Day coaches were provided for the itinerary that occupied to overflowing the second and third days' stay in the Birmingham district. On Tuesday visits were made to Ishkooda No. 13 ore mine, of the Tennessee Coal, Iron & R.R. Co., the No. 1 ore mine of the Woodward Iron Co. and the Muscoda No. 6 ore mine of the Tennessee Coal, Iron & R.R. Co. The party then went to Bayview and was entertained at a barbecue. At this place is a coal mine, an impounding reservoir and a village of the Tennessee company.

The coal mines of the Birmingham region have in general a character all their own, due partly, doubtless, to the influence of the adjacent and associated ore mines of the district and partly also in the case of the mines owned by the steel companies to the fact that the breakage of the coal is a matter of no importance though skips probably need not be a cause of coal breakage if properly handled. At Bayview the coal is raised in a huge skip on a slope driven through sandstone at an inclination of 26½ deg. The bed worked is the Pratt seam. The mine produces 2,400 tons a day. To those accustomed to the rapid movement at a shaft with cages the leisurely efficiency of the big skip is a marvel to behold. The coal is washed in three-compartment jigs. As this washery was described by H. S. Geismer in the issue of Oct. 9 it is not necessary to say more about it here.

The train then moved on to Edgewater, another mine

of the Tennessee company with a most unusual hoist having two drums in balance. One hoists from an upper landing at a depth of 238 ft. and another from a landing at 380 ft., 142 ft. below. They both hoist from the Pratt seam which is faulted at that point, the throw being about 140 ft. The drums are made of unequal diameters so that the hoist will raise a load from the lower landing in the same length of time as it will lower another load to the upper landing and vice versa. The clean coal in the bed is 56 in. thick.

The output has been 6,002 tons in a single day, but the mine produces regularly about 4,000 tons daily. The shaft which is 420 ft. deep serves an area of 4,000 acres which contains 30,000,000 tons of clean coal. About 1,200 men are employed. The main hoisting shaft is lined with concrete. The air shaft is 12 ft. in diameter, and the manway is 800 ft. long and measures 7x12 ft. The visitors inspected the coal washer, the hoisting and boiler houses, the machine shop, supply house, bathhouse and store.

The trip concluded with a trip to the Fairfield coke works of the Tennessee company and the Fairfield wire mill of the American Steel and Wire Co. and the members noted with interest the manufacture of wire fence, wire nails and barbed-wire.

In the evening the Industrial Relations Committee of the American Institute of Mining and Metallurgical Engineers held an open meeting in the Hotel Tutwiler addressed by Frank H. Crockard, president, Woodward Iron Co., the subject of Mr. Crockard's remarks being the industrial relations in the coal-mining industry of the Birmingham district. Mr. Crockard pointed out that the companies of the region felt to the full their obligation to pay fair wages, to see that checkweighmen were provided and to arrange for the settlement of grievances.

They did not believe that wages altogether out of line with those in the district for other kinds of labor should be paid by the coal-mining industry. They were insistent on the appointment of checkweighmen and in fact brought pressure to bear on their workmen to provide them. After providing for the settlement of grievances they were not pleased to find that none were presented, and they told their foreman and subbosses that they would hold them responsible for the failure of their men to present grievances which the companies felt sure existed.

After this expression of their displeasure and earnest intention to hear and redress grievances the complaints began to come in, and now the provisions for adjustment were being duly received and carefully adjudicated. The meeting was presided over by R. Dawson Hall. Simultaneously the directors with a representative group of institute members dined at the hotel.

The next morning, Wednesday, the party assembled on the train for a trip which embraced Ensley blast furnace No. 6, No. 1 steam plant and openhearth plant and the Fairfield car works and steel works of the Tennessee company, the plant of the Phoenix Portland Cement Co. and the Tarrant City pipe works of the National Cast Iron Pipe Co. At the Portland Cement works, lunch was served, and the party visited the open pit in which the limestone was being mined by steam shovels, the factory where the materials—limestone, shale also from the vicinity and a small quantity of gypsum—were crushed and mixed and where the mixture was calcined and ground.

Perhaps the most interesting visit was to the Tarrant plant. Here cast-iron pipe was being manufactured by the de Lavaud process. This process to quote Richard Moldenke's paper, which by the way was not read at the technical sessions, "consisted in rotating a steel mold at a high rate of speed, introducing therein the proper quantity of molten iron, which through centrifugal force is spread over the mold and this makes the pipe." The molten iron is introduced at bottom of the mold and gradually fed into it as it recedes at such a speed that the interior of the mold is covered evenly by the molten iron to the required thickness. No inner core is provided. The centrifugal action makes the iron thus cast unusually dense and therefore strong. In consequence without any reduction of strength it can be made only 75 per cent as heavy as is customary.

The bell is cast in the same way as the pipe proper and by the same operation. The pipe thus made is remarkably smooth but being cast in a water-cooled mold is too hard on its exterior surface. This chill is corrected in an annealing furnace in which the heat is gradually imposed and removed. After this the pipe is cleaned, dipped and tested. The company still makes the pipe by the sand-mold process, which takes 72 hr. for the completion of the entire operation from the making of the mold to the testing of pipe, both inclusive. The new pipe are made, annealed, dipped and tested in 3 hr.

In the evening of Wednesday a banquet was held at the Birmingham Country Club at which the speakers were William Kelly, J. V. W. Reynders and John McLeish, the last named being the Director of the Mines Branch of the Canadian Geological Survey. George Gordon Crawford presided.

Next morning the party visited Muscle Shoals dam

**Blast Furnace of Tennessee Company at Ensley, Ala.**

At this plant are six skip-filled blast furnaces each having four stoves which are heated by waste gases and which raise the blast to 1,300 deg. F.

which was explored from top to bottom, the members and guests going down the penstocks by ladders and thence down the Moody spreading draft tubes. A visit was made to nitrate plant No. 2 where nitrates were made by the cyanamid process. The plant will develop 80,000 hp. at low water and 600,000 hp. for 25 per cent of the time provided turbines and generating machinery are provided for that purpose. The intention is to install at an early date enough units to develop 240,000 hp. whenever that quantity of water power is available. Late that evening the party left for Washington arriving at midnight of Friday after several days of strenuous activity but with happy memories of a visit that none of the party will forget as long as he lives.

## News Of the Industry

### Soft-Coal Industry Takes Belated Steps To Meet Fuel-Oil Competition

National Coal Association Authorizes Program of Research—Interests of Coal and Oil Producers Similar, Both Suffering from Overdevelopment—May Join Hands to Effect Economies

BY PAUL WOOTON  
Washington Correspondent of *Coal Age*

That the bituminous-coal industry is taking cognizance as never before of fuel-oil competition was indicated clearly at the recent meeting of the board of directors of the National Coal Association. The board has given its unqualified approval to the research committee which Harry L. Gandy, the association's secretary, had set up without authorization on the chance that the directors would hold up his hands. Not only was a program of research authorized but the members of the board indicated clearly that the time has passed when the industry can afford to ignore the competition which oil is offering.

There have been fuel-oil menaces before. In the swing of the economic cycle this competition would diminish to the point where sight was lost of the fact that it has for many years been an important competitor. Oil and coal are competitive sources of power and heat. Ordinarily oil can compete importantly only when power is produced in internal combustion engines whose greater thermal efficiency, lighter weight and adaptability to small scale installation have offset a much higher unit price.

The extraordinary development of the gasoline engine has robbed coal of much of the increase which otherwise would have come in the consumption of that fuel. The average coal man does not realize that gasoline has been a serious competitor for thirty years, but the facts are that this country has an installation in automobiles of 400,000,000 hp., as compared with an installation of 70,000,000 hp. in steam-driven transportation. This gives an indication of the potential demand which would have been supplied in part at least by coal had it not been captured by gasoline.

There has been a keener realization of the competitive possibilities of fuel oil because it could be visualized burning in the same equipment which formerly used coal. In the past fuel oil menaces have been caused chiefly by the high cost of coal. The present invasion of fuel oil is made possible by the low price of petroleum. It was brought about largely by the simultaneous discovery in 1923 of six record-breaking pools, Smackover, Powell,

Huntington Beach, Santa Fe Springs, Long Beach and Tonkawa. All of these great pools reached the peak of their production within a few months of each other and contributed to the greatest overproduction of crude petroleum since the Cushing field days of 1914.

Instead of the interests of the coal producer and the oil producer being in conflict they really are identical. It is only natural that the oil producer, finding himself with a great supply which he cannot choke off, should seek new markets. The condition, however, which drives him into the boiler-fuel market is a very unsatisfactory one to him, just as an overproduction of coal makes for an unsatisfactory state of the coal business.

#### Too Many Mines and Wells

Oil and coal are suffering from the same trouble—the tendency to overproduce. There are too many mines and there are too many oil wells. The thought now is being put out from a high official source that there must be co-operative action within the industry to prevent waste and hold development in check until additional supplies are needed. While the idea is directed primarily toward preventing the production of oversupplies of oil there also is official consideration being given a joining of hands by the producers of the two great fuels in an effort to effect colossal economies.

While the present wave of fuel-oil competition has lasted longer than any of its predecessors the time will come when it will recede. In fact there are signs already that production at the new pools is on the downgrade. But unless constructive steps are taken to bring about co-operation to prevent overproduction, a new glut of oil will be forthcoming before long with the discovery of some other field or because of the present significant trend of carrying oil production to new depths.

Even if the United States should run through its reserves of flowing oil there will be new floods of it from Mexico, from the Caribbean, from South America, or some other source. These waves of overproduction will keep on coming. For that reason it is argued that men in the coal and oil in-

dustries should take common counsel and effect a revision of the antiquated laws which at present compel waste and overproduction. The competition is of a character that the coal industry cannot meet alone. If the price of coal be reduced through wage cuts or other expedients it simply will mean that the level of fuel-oil prices will be reduced. There can be no bottom to price when there is an oversupply which must be disposed of.

Fuel oil for domestic use is quite another problem. The industrial user will turn back to coal just as quickly as oil ceases to be the best bargain in B.t.u.'s. The domestic user is discovering that oil has more than its B.t.u. content. It is clean and convenient. The thousands of householders now using oil will not go back to coal if oil prices rise. They have been spoiled by the simplicity of the oil burner. They will not burden themselves again with the dust and the ashes of coal in this day of few domestic servants. It will be just as hard to change them as it would be to wean the anthracite users of New England from their diet of stove and chestnut. The bituminous industry must find a way to give coal the same convenience and cleanliness as oil now affords. The consensus is that this will not be particularly difficult if the coal producers will stimulate the necessary experimentation.

#### House Heating Antiquated

It is curious that the attention to fuel economy which has revolutionized power-plant practice in recent years has not been widened to include house heating. The average house-heating plant today is a medieval thing still burning lumps and paying fancy prices for them. Stoking still is done by hand. The toting of ashes is as prevalent now as one hundred years ago. Fuel is burned raw and waste gases go up the stack. Radiation losses average as high as ever and there continues to be alternate under- and overheating of rooms. In fact, all of the things which are regarded as bad boiler-room practice are the rule in the handling of house-heating plants.

If the National Coal Association will hold out sufficient inducements—and the producers of coal have more to gain than has anyone else—way soon will be found to burn coal as a powder or as a gas. Automatic stokers will be devised. Combustion will be controlled by thermostats. The question is more one of how and when rather than will it be done. It may take a long time to work out the problems if they are left to individual inventors working on shoestring resources, but if the research is properly financed results may be expected promptly.

## Ruhr Coal Syndicate Gets \$2,500,000 Credit Here

An acceptance credit to the extent of \$2,500,000, which a few weeks ago was under negotiation between representatives of the Ruhr Coal Syndicate and a group of American financiers, has finally been arranged, it became known last week, the American bankers in the transaction being Goldman, Sachs & Co. The credit is to finance the export of Ruhr coal, in which German industrialists such as the Krupps, Stinnes and others are interested.

This move is regarded as forecasting the participation of American bankers in the financing of other major European industries, especially since the Allies have insisted that the Ruhr coal operations constituted the backbone of the whole industrial program of Central Europe, with steel, iron and other industries absolutely dependent upon Ruhr coal.

## Penna Sees Black Future For Union Coal Fields

Phil H. Penna, secretary of the Indiana Bituminous Coal Operators' Association, is not optimistic concerning the coal industry in Indiana or in any union field for that matter, and he objects to the fact that a government report terms Indiana's business "good."

"There is no hope for the coal industry during the life of the Jacksonville agreement," stated Mr. Penna, referring to the contract executed by the United Mine Workers and the operators of the union fields at Jacksonville, Fla., last January.

"My opinion," Mr. Penna said, "is based upon two facts: First, that the nation is now taking its ordinary requirement of ten million tons weekly, and second, that the surplus of the non-union fields could be utilized and will be utilized, if the country ever requires it, before our coal will be wanted. With the nation getting its required amount now, and with a large surplus supply of non-union coal in store, how can the union operators expect a revival of the industry in their fields?"

Reports compiled by the Indiana Coal Traffic Bureau show an increase in production in the Indiana field within the last month of 225,204 tons, but it is of little consequence, according to Mr. Penna. The domestic demand probably is the cause of the increase, but the percentage of production which goes for domestic use is very small in normal times.

"During the week ending Sept. 27," he said, "the Indiana mines worked 41 per cent of potential time; the Illinois mines 50 per cent; the southern Ohio field 20 per cent; the Pittsburgh field 49 per cent, and the northern and central Ohio fields 66 per cent. The northern and central Ohio fields enjoy a much better business than the other fields named because they are close to the lakes and have the advantage of the lakes for shipping.

"The non-union fields of Kentucky work an average of 73 per cent, the Logan non-union field worked 63 per

## Union in West Kentucky Is Dying Hard

Miners in what is left of the union district 23, in western Kentucky, declare the resignation this month of President Lonnie Jackson and the appointment of West Ames to fill the vacancy signifies no change in the union no-surrender policy. The region has been on strike for six months and half of western Kentucky is working non-union. The former president is publicly declaring, however, that the Lewis policy of "no backward step" is dead wrong and that western Kentucky is being sacrificed to the bullheadedness of the union administration. He urges that a reduction in wages be allowed so that the union can continue in the region. Jackson has favored a wage cut ever since the strike started, but Lewis ordered him to continue the strike or resign. He resigned.

cent during the week ending Sept. 27, the Pocahontas non-union field worked 75 per cent, the Winding Gulf non-union field worked 57 per cent, the Panhandle non-union field worked 61 per cent, and the Westmoreland non-union field, near the Pittsburgh union field, worked 57 per cent.

"The non-union fields, the report shows, are working about two-thirds of the time, while the Indiana mines are working much less than half time."

## Will Strive to Bring Public And Operators Closer

Instructing its committees to speed up their work in an effort to better serve the public, the National Coal Association, through its board of directors, in session at Washington last week, took steps to broaden the sphere of the association's activities. The association purposes, through its own efforts, bringing about a more satisfactory use of coal and a closer relationship between operators and their customers and the public.

The submission of a questionnaire to retail dealers and household users of coal in order that the industry may definitely ascertain the public viewpoint, was authorized at a meeting of the new Research Committee of the association and later confirmed by action of the board.

To bring about uniform accounting methods in connection with Bureau of Internal Revenue reports, a special tax and cost accounting committee was authorized.

There was apparent a desire to eliminate any basis for criticism, and the meeting is said to have been one of the most successful the National Coal Association has ever held. It was attended by directors from 14 bituminous coal producing states and was presided over by S. Pemberton Hutchinson, of Philadelphia, the new president.

## Miners Call Off Strike at Glen Alden Collieries

Scranton, Pa., Oct. 20.—The recent strike called by the general grievance committees of the Glen Alden Coal Co. miners in Luzerne and Lackawanna valleys has ended. The strike was called in defiance of the district and International union leaders. W. W. Inglis, president of the coal company, as a member of the conciliation board, sent a telegram to International President Lewis of the miners' union calling his attention to the threatened strike and Mr. Lewis in turn notified the district leaders to try to halt the walkout, but in spite of his efforts several thousand men failed to report for work on Oct. 15. It is said that because of the illegal walkout the charters of certain locals at Glen Alden mines will be revoked by the International union.

## New York Bids Numerous and Wide in Range

Bids opened on Oct. 14 by the Board of Purchase of New York City for furnishing and delivering to various city departments 68,917 net tons of various sizes of anthracite, resulted in the following tenders:

Borough of Manhattan—10,589 tons egg coal, \$12.57 to \$13.98 per ton; 1,667 tons stove coal, \$12.96 to \$14.62; 605 tons chestnut coal, \$12.93 to \$14.62; 810 tons pea coal, \$8.87 to \$9.55; 1,170 tons broken coal, \$11.93 to \$13.50; 12,000 tons No. 1 buckwheat, \$5.76 to \$6.50, and 84 tons Georges Creek Cumberland coal, \$8.10 to \$10.50.

Borough of Brooklyn—8,300 tons egg coal, \$12.47 to \$12.62 per ton; 1,836 tons stove coal, \$12.61 to \$14.62; 390 tons chestnut coal, \$12.61 to \$14.62; 146 tons pea coal, \$9.04; 10,000 tons No. 1 buckwheat, \$5.76 to \$5.89, and three tons Georges Creek Cumberland coal, \$9 to \$9.04.

Borough of Queens—2,925 tons egg coal, \$12.61 to \$13.50 per ton; 124 tons stove coal, \$13.25 to \$14.25; 232 tons chestnut coal, \$12.98 to \$14.62; 144 tons pea coal, \$9.04 to \$9.41; 3,000 tons No. 1 buckwheat coal, \$5.76 to \$6.40, and three tons Georges Creek Cumberland coal, \$7.90 to \$9.04.

Borough of the Bronx—4,005 tons egg coal, \$12.62 to \$13.73 per ton; 1,131 tons stove coal, \$13.04 to \$14.62; 149 tons chestnut coal, \$12.93 to \$14.62; 850 tons pea coal, \$8.87 to \$9.55; 5,000 tons No. 1 buckwheat coal, \$5.73 to \$6.40, and 24 tons Georges Creek Cumberland coal, \$8.10 to \$9.04.

Borough of Richmond—805 tons egg coal, \$12.13 to \$13.90 per ton; 61 tons stove coal, \$12.48 to \$14.62; 150 tons chestnut coal, \$12.48 to \$14.62; 21 tons pea coal, \$9.11 to \$10.50, and 1,000 tons No. 1 buckwheat, \$5.93 to \$6.75.

For furnishing and delivering 230 net tons of egg coal to the Bronx Park Department bids ranged from \$12.83 to \$14.25 per ton.

The time of delivery of the above tonnages, with the exception of that for the Bronx Park Department, is to March 31, 1925. The tonnage for the Park Department is to be delivered by Dec. 31 of this year.

## Rate from Pocahontas Field To Washington Lowered

The Interstate Commerce Commission has authorized a departure from the fourth section of the Interstate Commerce Act, which will give Washington, D. C., a much lower rate on coal from the Pocahontas field. The rates which will be in effect as soon as the tariffs can be published are \$2.84 from the Pocahontas district, \$3.09 from the Thacker district, and \$3.19 from the Kenova district. The effort to effect this departure from the fourth section was a part of the movement toward making available at lower prices substitutes for anthracite. When the commission last year undertook its investigation to ascertain whether or not substitutes for anthracite could be made available in New England and the North Atlantic states, George S. Pope, manager of the Government Fuel Yard in Washington, asked that the Norfolk & Western R.R. be required to establish rates from the Pocahontas field to Washington on the same basis as those in effect from the New River field.

The Norfolk & Western was willing to put the rates into effect, but a difficulty arose by reason of the fact that the rates from the Pocahontas field to points on the Southern Ry. between Lynchburg and Washington were higher than the proposed rate to Washington. For this reason it was necessary to obtain authority before a lower rate could be charged to Washington than was in effect to intermediate points.

## End West Virginia Strike After Six Months

A strike of 800 miners of the Kelly's Creek Colliery Co., at Ward, W. Va., which has dragged along for six months, came to an end Oct. 17 when it was announced that the concern had signed an agreement with the United Mine Workers of America, under the 1923 scale. A similar contract was signed by the Miners & Consumers Coal Co., employing 130 men, at Morrisville, W. Va.

These two companies are the only concerns in this field operating under union agreements. Negotiations with other companies are under way.

## Keeney Says Miners Should Not Vote for Davis

Labor organizations should oppose the candidacy of John W. Davis for the presidency, said C. F. Keeney, former president of district No. 17, of the United Mine Workers (West Virginia), and William Blizzard, an aide, in an interview in Indianapolis, Ind., recently. The two men assert that they represent District 17 in opposing the candidacy of Mr. Davis on the ground that he has the support of "the great anti-union combine of industrial interests in West Virginia which has seized control of government there and converted the agencies of public authority into instruments of private warfare upon labor unions and organizations of workers."

## Coolidge Decries Federal Control of Industries

Speaking at Philadelphia, President Coolidge opposed government control of railroads, industries and utilities. "If the people lose control of the arteries of trade and the natural resources of mechanical power, the nationalization of all industry could soon be expected," the President said. "Through the breaking down of the powers of the courts lies an easy way to confiscation of property. With railroads and utilities under political control, the domination of a group would be so entrenched in government that the privilege of citizenship would consist largely in payment of taxes. Leave the people in the ownership of their property."

## Says Big Four Should Build Connection to Dering Mine

The Big Four R.R. should be ordered to make switch connections with the coal mine of the J. K. Dering Co. at Eldorado, Ill., in the opinion of W. P. Bartel, of the staff of the Interstate Commerce Commission, in his report to the commission. The coal company alleges that the failure of the Big Four to establish connections with its siding has made impossible the full development of its 3,400 acres of coal land in Saline County, where it has 30,000,000 tons of coal still unmined. At present the property is served only by the Illinois Central, which is not in a position to handle the 3,500 tons which the mine can produce daily.

The railroad company contends that the building and maintenance of such track as the coal company has constructed is not authorized by its state charter; that such a track, by reason of contracts with the Illinois Central and the Southern Illinois Railway & Power Co., under the law of Illinois, is a public track and that an order requiring the extension of the Big Four tracks in effect would be the taking of property without due process of law; that the connection is not practicable and will not furnish sufficient business to justify its construction; and that the proposed connection with a new railway has not been authorized under the state law. It is the conclusion of the staff of the Commerce Commission that there is sufficient business to justify the connection and that it can be put in with safety.

## Coronado Case Up Again

The latest phase of the noted Coronado coal case, an appeal by Finley, receiver, against the United Mine Workers of America, will be heard by the U. S. Supreme Court on Monday, Jan. 5, a motion to advance the argument having been granted Oct. 20. The case involves the financial responsibility of the international union and subordinate organizations for damages to mining property in Arkansas suffered during strike disorders. This is the second time the issue has been before the Supreme Court.

## Coke Output in 1923 Makes Record for the Industry

Output of beehive and byproduct coke combined in 1923, according to final returns by the U. S. Geological Survey, was 56,977,000 net tons, the largest in any year in the history of the industry, even exceeding the wartime maximum. The final figures are 2.7 per cent higher than the preliminary estimates published Jan. 15, 1924.

Of the production, 37,597,664 tons, valued at \$257,591,318, or about 66 per cent of the total, consisted of byproduct coke, while 19,379,870 tons, valued at \$115,905,580, was beehive coke. The average yield of coke from coal in the case of byproduct fuel was 69.3 per cent, while in the case of beehive coke it was 64.4 per cent.

The returns involved 11,156 byproduct ovens, of which 3,094 are in Pennsylvania, 1,619 in Ohio, 1,213 in Indiana and 1,196 in Alabama, with the others scattered. The byproduct coke used in blast furnaces or affiliated work amounted to 27,055,397 tons, valued at \$168,379,600.

Merchant sales of furnace byproduct coke totaled 1,460,538 tons, valued at \$9,847,055, while sales of byproduct coke for foundry use aggregated 1,897,955 tons, valued at \$19,995,342. Byproducts obtained from coke oven operations and sold in 1923 were valued at \$112,075,945. Of this total 884,952,912 lb., valued at \$25,954,413, consisted of ammonia sulphate as against a production of 915,926,762 lb. Motor benzol products totaled 80,467,883 gallons, while the amount sold exceeded this somewhat and consisted of 80,480,326 gallons, valued at \$13,145,833.

Of the beehive coke produced last year, 6,437,771 tons, valued at \$39,326,693, consisted of merchant sales of the furnace grade, while foundry beehive coke sales amounted to 1,702,764 tons, valued at \$12,259,196. The production of beehive coke reported came from 62,349 ovens, of which 37,578 are in Pennsylvania, 8,055 in West Virginia, 6,199 in Alabama, 3,284 in Virginia, 1,767 in Tennessee, 1,758 in Colorado, and 1,030 in New Mexico, the remainder being scattered.

## Important Cases Reassigned By Supreme Court

Among the important cases set for argument before the U. S. Supreme Court on Nov. 10, which have been reassigned for Nov. 17, are the Cranberry Creek Coal Co. case questioning the legality of the anthracite tax imposed in the State of Pennsylvania and one involving the constitutionality of the Kansas Industrial Relations Act, attacked by the Charles Wolff Packing Co.

Coal to the extent of 3,121,576 tons was used in connection with the manufacture of glass during 1923, the Bureau of the Census reports. Similar figures covering other industries are as follows: Photo-engraving, 2,748 tons; enameling and japanning, 13,923 tons; lasts and related products, 12,014 tons.

Finance Coal Storage by  
Recourse to Banks and  
Employers, Engineers Say

Banks will finance storage for employers, and employers will finance storage for wage earners, according to a report just made by the Coal Storage Committee of the American Engineering Council on the feasibility of financing coal in storage.

Because of financial and housing conditions many wage earners cannot store their coal without financial aid in some form. "Several employers," says the engineers' report, "purchase and store a quantity of coal which is subsequently sold to employees at cost. A few render aid only in periods of severe coal shortage. Another obtains coal from a dealer, paying in full and deducting payments in reasonable installments. Several sell their byproduct coke and coke breeze at cost.

"In one company an employee mutual benefit association forms to pool purchases for members. A number of plants operate and handle on a club plan. One concern allows employees to select a dealer to whom the company pays in full, deducting the amount from wages in equal installments.

"Another organization purchases a run of mine coal and picks out lumps which are sold to employees at very low cost, the company utilizing the remainder. One company charges cost plus a reasonable amount to cover the expense of a man competent to handle purchases and delivery."

In general, according to the American Engineering Council's report, it may be said that satisfactory arrangements can be made to finance the storage of coal and very much in the same way that other transactions are financed, that is by bank loan, deferred payments, or carrying the account with operating capital.

Howard W. Showalter

President of the Diamond Coal Co., Fairmont, W. Va., and named by Governor Morgan as one of the delegates to represent West Virginia at the annual convention of the American Mining Congress, at Sacramento, Cal., Sept. 29-Oct. 2.

Coal Consumption and Power  
Output by Utilities Climb

Electric public-utility plants consumed 2,948,998 net tons of coal during August, according to a report by the Geological Survey. This compares with 2,787,724 tons consumed in July and 2,679,859 tons in June, according to revised figures. Fuel oil consumed by utility plants during August totaled 1,498,730 barrels, compared with 1,431,310 barrels in July and 1,344,632 barrels in June.

The average daily production of electricity by public-utility power plants during August was 152,700,000 kw.-hr., which is about 2½ per cent greater than the daily output during July.

Dominion Government to  
Aid Shipment of Coal to  
Central Canadian Districts

Shipment of Maritime Provinces coal to central Canada is to receive government assistance, providing the railways make reductions in their present published freight rates on coal. Under an order-in-council, just passed by the Dominion Cabinet, Charles Stewart, Minister of Mines, is enabled to pay a subvention of ¼c. per ton mile on coal shipped wholly by rail from eastern Canada to stations in Ontario and Quebec west of Riviere du Loup. On waterborne coal from the Maritime Provinces the same subvention is allowed on the railway haul from the port of transshipment to destination.

This assistance will be given out of an appropriation voted last session by Parliament to aid in the transportation of Western and Eastern coal to central Canada. At that time it was thought that with this aid considerable quantities of coal from Alberta would be placed on the markets in central Canada. But the prolonged strike in that Western province makes such a development unlikely this season. Of the \$200,000 voted not more than \$150,000, according to the terms of the order-in-council, may be used to assist the transportation of coal from eastern Canada.

An important restriction in regard to the subvention is that the government will not give more than 50c. a net ton on any single shipment, nor are payments to be made where Canadian coal is not in competition with United States coal. No grant will be given on shipments for use on railway locomotives.

The Dominion Fuel Board, which will administer the grant, reports that the railways concerned have already agreed to make a reduction in their coal rates.

Output and Value of Coal Produced in the United States, by States, in 1923

## Jury Must Convict Before Contempt Sentence

Section 22 of the Clayton Act requiring conviction by a jury as a condition precedent to sentence for contempt of court, if a trial before a jury is demanded, constitutes a valid restriction upon the inherent judicial powers of a U. S. district court, the U. S. Supreme Court held Oct. 20 in replying to a question from the Sixth Circuit Court of Appeals.

The question arose in the appeal of S. C. Sandefur, who was sentenced for contempt by a federal district court in Kentucky on a charge of having violated an injunction against the use of threats and violence during a strike against the Canoe Creek Coal Co. Sandefur was denied a trial by jury on the contempt charge, and appealed, whereupon the Circuit Court of Appeals referred the construction of this clause of the Clayton Act to the Supreme Court for interpretation.

At the same time the Supreme Court, in the appeal of Sam Michaelson and others who were convicted of contempt in Wisconsin on charges of violating an injunction issued the Chicago, St. Paul & Omaha R.R. during the shopmen's strike in 1922, went more fully into Section 22 of the Clayton Act and held that the striking employees were entitled to trial by jury on contempt charges. The District Court and the Seventh Circuit Court of Appeals in this case had held this part of the act unconstitutional. This decision was reversed by the Supreme Court in a decision rendered through Justice Sutherland.

## Trade Associations to Study Uniform Cost Accounting

Representatives of more than 300 trade associations have been invited to attend a conference on uniform cost accounting to be held at the Congress Hotel, Chicago, Oct. 28 and 29. The meeting will be the third of a series held under the auspices of the Department of Manufacture of the Chamber of Commerce of the United States for the purpose of furthering interest in systematic cost accounting work.

The preliminary program for the Chicago conference lists two subjects for consideration on the opening day. One of these is "The Bankers' Interest in Uniform Cost Accounting," to be discussed by J. W. O'Leary, vice-president of the Chicago Trust Company, and the other "The Printer, Uniform Cost Accounting, and the Federal Trade Commission." The latter subject will be discussed by two speakers who will go into the question of the Federal Trade Commission's attitude toward uniform cost accounting activities.

In announcing the preliminary plans for the meeting, E. W. McCullough, manager of the Chamber's Department of Manufacture, makes the point that the adoption of uniform cost accounting by an industry does not mean the destruction of individual systems now in use but only adjusting them in harmony with uniform methods. "Few individual systems," he says, "attain the accuracy and facility of operation found in uniform systems built by the

## Boys Build Pretty Bonfire With Stolen Dynamite

On the basis of information by school teachers that schoolboys had dynamite in their possession, Pottsville (Pa.) police made an investigation last week and announced that three pupils, all less than twelve years old, had confessed taking a box of dynamite from the Sherman Coal Co. and had used the sticks for kindling wood. The boys said they had built a fire with forty of the sticks because they made such "pretty blue flames." The police confiscated the remainder of the loot.

members of an industry who, after careful study, have combined the best found in individual practice, adding to it by way of improvement and advance in technique found in other lines. The advantage of the same practical revision of a uniform system from time to time should not be overlooked."

## World Coal Output for First Half of This Year 655,000,000 Metric Tons

World production of coal during the first half of 1924, according to the U. S. Geological Survey, was approximately 655,000,000 tons, or at the rate of 1,310,000,000 tons a year. This rate was less than that of 1923 but far above 1922 or 1921, and almost equal to the output of 1920. The present level of coal production, however, is still below that of 1913.

In comparison with the corresponding period of 1923 the preliminary figures show a decrease of about 5 per cent. The largest element in this decrease was the lessened production of the United States, as American con-

## Names N. C. A. Committee to U. S. Chamber of Commerce

Representatives of the National Coal Association at the second mid-year meeting of the Eastern Division of the Chamber of Commerce of the United States, which will be held in Washington on Oct. 23 and 24, have been appointed by S. Pemberton Hutchinson, president of the association, as follows: C. W. Watson, president, Consolidation Coal Co., New York City; Michael Gallagher, general manager, M. A. Hanna Co., Cleveland, Ohio; C. C. Watt, president, Loyal Hanna Coal & Coke Co., Philadelphia, Pa.; John L. Kemmerer, president, Whitney & Kemmerer Coal Co., New York City; William A. Evans, vice-president, National Coal Co., New York City; C. E. Bockus, president, Clinchfield Coal Corp., New York City, and J. G. Bradley, president, Elk River Coal & Lumber Co., Dundon, W. Va. Other representatives to the Northern Central, Southern Central and Western Division meetings which will be held at Indianapolis, Memphis and Los Angeles, respectively, will be announced later.

sumers drew upon the heavy stocks they had accumulated last year.

Among the European countries the United Kingdom and Poland also show a decline in comparison with 1923. This decline was more than offset by the partial recovery of German production from the low levels touched during the occupation of the Ruhr. Most of the other European countries also increased their output.

The following table, prepared by W. I. Whiteside, of the Section of Foreign Mineral Reserves, summarizes all information received by the Geological Survey up to Oct. 1 and is subject to material revision as final official figures are received. Lignite and brown coal are included; where possible they are shown separately.

## Practical Pointers For Electrical And Mechanical Men

### Few Bond Testers Tell the Truth But Here's One That Will

Instruments Usually Fail To Give Correct Indications of Resistance of Bonds—Accurate Results Obtained by Twin Millivoltmeter Type of Tester

AFTER almost a year's study of methods of bonding and types of bonds, our company decided that much of the controversy over bonding was due to the fact that no instruments were made which gave a correct indication of the resistance of a bond. We therefore designed a bond tester which gives the exact resistance of a bond. After thoroughly proving its suitability we have had one built for each of our larger operations.

The contact bar looks much the same as most types, but whereas the contacts before were all solidly fixed, 3 ft. apart, on ours only the middle contact is fixed; the outer clips are movable. With the old contact bar, where the distance between contacts was fixed at 3 ft., when testing a short 6-in. bond, the result was that six inches of bond and thirty inches of rail was being compared with three feet of rail. Thus this type of tester greatly favored the short bond.

On ours, the middle contact is placed at one end of the bond, an end contact on the bar is set at the other end of the bond and the other contact is set to cover an equal length of rail. Thus with the 6-in. bond, both end contacts would be set six inches from the middle clip and we are comparing six inches of bond with six inches of rail,

This is the Truth-Telling Meter for Bonds

Two millivoltmeters indicate the voltage drop across the bonded section and an equal length of rail. The ratio between the two readings tells the condition of the bond.

giving the correct relation between their resistances.

The contacts are pieces of hack saw blades clamped in a copper terminal clip. The fixed central contact has a compression spring arrangement to allow it to adjust itself vertically to an uneven rail joint, giving a solid contact on all three clips.

The testing instrument itself is of entirely different design from most instruments. Many bond testers are based in some form of a Wheatstone bridge. One prominent type has the bond balanced against three feet of rail, plus the resistance necessary to form a balance. This resistance is cut in by a sliding arm which also carries a pointer showing the proportion cut in. Another make replaces this variable resistance by a sliding contact on the rail which is adjusted to form a balance. The amount of rail necessary for this balance can then be measured. Two pairs of fixed resistances are often used in these types giving proportions of 1 to 1 or 10 to 1.

Our bond testing instrument is of the twin millivoltmeter type. Its general appearance is shown in the illustration. Instead of having to balance a bridge, always a more or less delicate operation, the operator merely compares the two millivoltmeter readings. As shown in the wiring diagram there are two resistances  $R$  and  $R'$  connected in series with each millivoltmeter, which may be shunted by a

double-pole switch  $S$ . This switch is shown in the upper right hand corner of the picture. In the normal position it is open and the resistance is cut in, when closed it short-circuits the resistance only as long as the button is held in. This is so that the meters will not be accidentally connected directly across a defective bond.

When making a test, the switch is first left open; afterwards it is closed if the bond is intact. The millivoltmeters are ruggedly constructed with 0-100 millivolt scales. The double-pole double-throw switch ( $P$  in the wiring diagram) is shown as the pointer near the center of the picture illustrating the meter it is provided to easily reverse the connections to the meters in case the readings are reversed.

When the instrument is in operation lead  $L 2$  is connected to the center contact bar clip and  $L 1$  and  $L 3$  to the end contacts. These clips are adjusted to cover the bond and an equal length of rail. If the readings of the meters are reversed, turning switch  $P$  will change the connection. If the readings are sufficiently low the switch  $S$  is pressed and the voltmeters are connected directly to the rail while if

Check the Bond Against Equal Rail Section

Unless the bonded section of the rail is compared with an equal length of the same size rail incorrect results are obtained. A bond-testing outfit must be adjustable to obtain accurate results.

the readings are high the bond is immediately pronounced defective. With the resistance cut out, readings of each meter are taken and the ratio found.

Contact Makers Which Form Good Connections

Rigid contact bars and terminals will not fit uneven rails. Self-adjusting terminals form best connections and at the same time protect the instruments. Tested leads between the contacts at the rail and the instruments are also necessary for accurate readings.

Internal Connections of Instrument

The line terminals  $L 1$ ,  $L 2$  and  $L 3$  are connected to the corresponding point on the contact bar applied to the rail and bonded section. Series resistances  $R$  and  $R'$  protect the millivoltmeters  $V$  and  $V'$ .  $S$  is a short-circuiting switch to shunt these resistances.  $P$  is a polarity-reversing switch.

This is then compared with that given in the table, which is pasted in each instrument case. If it is higher than that shown in Bond Limit Value Table I, the bond is defective.

These bond testers have been in use for some time at our mines and are considered very satisfactory.

F. FRAZER MACWILLIAMS,  
Power Department.

Cresson, Pa.

### Keep Truck Wheels Lined And Stop the Wiggle

Many bus and truck operators are not aware that the front axles and steering knuckles are so designed that when the wheels are mounted they assume an angle in relation to the chassis frame, both in a vertical and horizontal position; then again the front axle is mounted on the springs in such a manner as to form a slight angle with the chassis frame. Altogether we have three different angles to consider.

The amount of angularity in each case is determined accurately when the vehicle is built and must be so maintained during its operation. Difficult steering, rapid tire wear and even loss of performance ability may be the penalties for neglect of this little-considered point.

The first of these three angles is under-gather, sometimes known as cambre, or incorrectly as dish, which consists of a slight outward leaning at the top of each wheel. This serves several purposes. It places the wheels more nearly perpendicular to the crown of the road. It converts some of the normal radial load on the wheel bearings into a thrust inward, thereby relieving the axle spindle nut of thrust. It gives greater stability against side-thrusts, as in rounding curves, because the inner wheel is always inclined slightly inward of the turn, so that some of the thrust is taken endwise by the spokes, or edgewise by the disk, in a disk wheel, where there is greater strength.

#### WHY WHEELS GRIND

But an inclined wheel has a natural tendency to travel in a circle instead of in a straight line, and if it is constrained to do the latter its tire will no longer roll straight along the road, but will continually grind, thereby wearing rapidly and consuming extra power. To correct this tendency, therefore, the second kind of inclination, namely fore-gather or toe-in is used. This consists of drawing together the front wheels so they are "pigeon-toed." If this fore-gather is figured correctly for the amount of under-gather, the wheels will practically have a true rolling contact and will roll straight.

Third among the trinity of inclinations of motor truck front wheels is what is known as the castor. This is an inclination of the axle itself, whereby the steering knuckles are not vertical, as we usually think of them, but lean backward at the top. This has the same effect as the off-center pivoting of the castors on a piece of furniture. It tends to make the truck travel in a straight line. If it were not for this castor effect, there would

### Automatic Brush Sweeps Dust From Pan Conveyor

Finely divided particles of coal that cling to the flights of a pan conveyor should be removed concurrently with

Dust Collector on Pan Conveyor

This device consists of a brush held in contact with the return flights of a pan conveyor under the tension of two springs thus sweeping to the ground the coal dust that accumulates.

be continual tendency for the truck to run off the road and when the wheels were turned the driver would have to "fight the wheel" to straighten out.

The correct amount of under-gather, fore-gather and castor, of course, varies with each make of vehicle so that in order to keep them as they should be, the correct measurement for the particular truck must be known.

On trucks, the correct amount of under-gather is  $2\frac{3}{4}$  in. By this is meant that the wheels are  $2\frac{3}{4}$  in. closer together at the bottom than at the top, measured at the wheel rim, not the tire rim. This is correct only for 36-in. solid tires. For other sizes the difference in the measurement should be as follows: 32-in. solid or cushion,  $1\frac{1}{8}$  in.; solid or cushion,  $1\frac{1}{4}$  in.; 32-in. pneumatic,  $1\frac{3}{8}$  in.; 34-in. pneumatic,  $1\frac{1}{2}$  in.; 36-38-40 in. pneumatic,  $1\frac{3}{4}$  in.

There is no adjustment for under-gather, as this is obtained by the manner in which the knuckles themselves are machined. These knuckle forgings are so exceedingly stiff that it is unlikely that they will ever become bent. The only things which can change the under-gather, therefore, are wear or faulty adjustment of the wheel bearings, wear of the steering knuckle pin bushings, or rarely, a sprung axle center. Straightening the axle center is the obvious remedy, but it should be heated at the center only, and not more than to a blood-red heat, and then straightened in a press until the steering knuckle pins are parallel. It should then be cooled in oil.

Fore-gather is obtained by the adjustment of the tie rod. The latter is a straight tube running across the front of the axle, having ball sockets screwed on each end. One of these ball sockets may be removed with the ball from the steering arm and adjusted by loosening the two clamp bolts and screwing the ball retainer in or out.

the formation of the deposit. Otherwise, if the conveyor is in a slope, the accumulation becomes so heavy that it soon breaks off in large greasy lumps and falls into the conveyor pit at the bottom of the incline or is deposited on the floor along the entire length of the conveyor. As several tons of this fine sized slack will be thus scattered in one day by a conveyor having a capacity of say 300 tons an hour, clean-ups become imperative. The job cannot be performed economically or entirely satisfactorily by a man with a broom and a shovel because the surfaces on which the dust is deposited are not readily accessible. Consequently, much time is consumed in gathering the dust by this manual method.

At the slope mouth of the No. 14 mine of the Island Creek Coal Co., Holden, W. Va., an automatic brush device is rigged up that sweeps from the pans the dust that accumulates during each round of the conveyor. The device is simple and easily installed. A brush, as long as the conveyor is wide, is attached to two fulcrum bars and held in contact with the return strand of the conveyor by two tension springs as shown in the accompanying illustration.

The measurements controlling this adjustment are taken between the flanges of the rim at the extreme front and rear of the wheels. On Mack trucks with 36-in. solid or cushion tires, the difference between these measurements should be  $\frac{3}{4}$  in. For other tire equipment the difference in measurement should be: 32-in. solid or cushion,  $\frac{3}{4}$  in.; 34-in. solid or cushion,  $\frac{3}{4}$  in.; 32-in. pneumatic,  $\frac{3}{4}$  in.; 34-46-38-40 in. pneumatic,  $\frac{3}{4}$  in.

#### AGE MAKES ADJUSTMENTS NECESSARY

The amount of castor or axle tilt depends upon two considerations, the mounting of the spring on the axle, and the shape and position of the spring itself. A wedge-shaped saddle is inserted between the spring and the spring pad on the axle, and in addition the front spring is mounted on the frame so that its front end is higher than its rear. Sometimes after long and continuous use the spring becomes somewhat distorted from its original form, though still capable of doing its work. In this case, the castor may be affected.

To determine the amount of castor a plumb line should be dropped from the lower edge of the front of the steering knuckle to the floor and the spot marked. A straight edge should then be laid along the steering knuckle, so that it bears on the upper and lower barrels and back of the lip of the central shroud. It should touch the floor  $\frac{1}{8}$  in. ahead of the spot previously marked on the floor. The amount of castor can be varied by shimmed either end of the spring seat.

Too much castor makes turning more difficult, since the front of the truck is actually lifted when the wheels are turned. With correct castor the maximum amount of lift will be 0.017 in.

# Production And the Market

## Soft Coal Market Shows Increased Irregularity But Trend Continues Upward

The bituminous coal market in general is holding its own quite well, though the gains are strikingly uneven; in fact there have been recessions here and there—probably only temporary in most instances. The New England trade continues to show marked strength, with prices headed upward. Unseasonably mild weather in most other sections of the country, however, has had a tendency to take the edge off demand, causing a return in some cases of the hand-to-mouth policy of buying. Western Kentucky is a notable case in point, the brisk spell having tapered off to such an extent that distress coal is now in evidence there. As so often happens, the first quickening in demand proved so tempting to many hungry for business that there has been an over-production in some fields, which with warm weather caused the inevitable setback.

### Trade Barometers Encouraging

Such barometers of trade as car loadings continue to give encouragement regarding general business conditions, despite the prominent part played by grain loading in the weekly reports. Equipment buying by the railroads also continues apace, orders for 1,900 freight cars having been placed by the carriers during the third week of October.

Coal Age Index of spot prices of bituminous coal again advanced last week—for the seventh consecutive time—standing on Oct. 20 at 176, the corresponding price for which is \$2.12. This compares with 174 and \$2.10 respectively on Oct. 13.

There was a slight reaction in activity at Hampton Roads last week, dumpings of coal for all accounts during the seven-day period ended Oct. 16 totaling 326,124 net tons, compared with 340,447 tons handled during the preceding week.

Coal continues to move up the lakes in steady volume, despite the many predictions that it would begin to fade

out by this time. Dumpings at Lake Erie ports during the week ended Oct. 19, according to the Ore & Coal Exchange, were as follows: For cargo, 735,770 net tons; for fuel, 40,787 tons, compared with 737,102 and 40,547 tons respectively during the preceding week.

Bituminous coal output continues to increase slowly, production during the week ended Oct. 11, according to the Geological Survey, totaling 10,548,000 net tons, a gain of 273,000 tons over the week ended Oct. 4, when 10,275,000 tons was produced, according to revised fig-

ures. The rate of output now is not far behind that of 1923, though it is still far below that of 1920. Anthracite production rebounded sharply during the week ended Oct. 11, when 1,737,000 net tons was the total compared with 1,425,000 tons during the preceding week.

Producers are moving anthracite without much difficulty, but retailers still feel, despite a slow, steady gain, that business is not all that it should be. Stove is in steady demand, with chestnut a close second. Egg is lagging somewhat and pea is rather hard to move. Steam coals are holding their own fairly well. Independent prices are firm. Most of the mines flooded by the recent heavy rains are resuming production, only a few having failed to get under way.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
Sept. 27.....	11,347,000	10,140,000
Oct. 4 (a).....	10,699,000	10,275,000
Oct. 11 (b).....	10,953,000	10,548,000
Daily average.....	1,826,000	1,758,000
Cal. yr. to date (c)...	432,665,000	352,896,000
Daily av. to date.....	1,799,000	1,463,000

#### ANTHRACITE

Sept. 27.....	1,959,000	1,942,000

Oct. 4.....	312,000	138,000
Oct. 11.....	284,000	129,000
Cal. yr. to date (c)...	15,047,000	7,726,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

## Midwest Market Is Slower

The continued warm weather throughout the entire Middle West has shown its effect on every size from every field, although Franklin, Williamson and Saline counties in Illinois still are far behind on lump orders, which is due to short running time. No new business has presented itself. Domestic egg and nut sizes are somewhat easier with a tendency to cut prices. There is still a good deal of "no-bill" coal. Operators in this field will cut prices on their surplus only where they feel it will not harm them, storing the coal rather than slashing prices.

Screenings will bring only what the buyer is willing to pay. Where the larger mines are holding firm at \$1.40@ \$1.50 for 1½ in. and 2 in. screenings, respectively, off-grades move at \$1@ \$1.25. Central Illinois fields are working more regularly than in southern Illinois, holding the price on 6 in. lump to \$3, selling other sizes at the best price obtainable.

Indiana Fourth Vein is fairly firm; mines are not operating steadily and there seems to be a demand for about what is offered for sale. Fifth Vein operators are having some difficulty in moving tonnage. Indiana screenings prices are from 80c. on Fifth Vein to \$1.25 on Fourth Vein.

Western Kentucky is much easier to obtain; operators are accepting orders and ship them promptly at from 10c. to 25c. off the list price on domestic sizes. Their screenings

are obtainable at 70c.@ \$1. Pocahontas screened lump and egg cannot be had lower than \$4.50@ \$4.75. Old line companies' mine run is holding firm at \$2@ \$2.25, but considerable good quality Pocahontas and New River mine run from independent operators is offered through jobbers at \$1.50.

There has been a slight let-up in the demand for domestic coal on account of the warm weather in southern Illinois. Lump and egg are holding up well but nut and the other sizes are a drag on the market. Steam coal is unusually slow and a number of mines are storing it. Many mines are unable to work full time because of unbilled coal and other mines are unable to start up because of no market for these sizes. Prices are unchanged, however. Railroad tonnage continues fair. Car supply is good. Mines are averaging three to four days a week.

In the Duquoin and Jackson County fields domestic conditions are good. Mines are getting three days a week, but are unable to sell steam sizes. The Mt. Olive district shows greater activity than elsewhere considering its dormant condition for the last six months. There is good movement for domestic and railroad coal and steam seems to be moving better here than in any other field. Mines are getting four and five days a week. Conditions are still bad in the Standard field, many mines selling coal below cost on account of the steam market, and nearly all of them have unbilled coal on hand all the time.

\* Net tons, f.o.b. mines. † Advances over previous week shown in heavy type, declines in italics.

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

Mild weather has enabled St. Louis dealers to begin to get caught up. Business is good and coal is plentiful and nearly all dealers have a good supply on hand. Wagonload steam is picking up, but carload steam is still slow. Country domestic conditions show improvement for the better grades of coal, but country steam is slow with no change in prices. Domestic demand is principally for higher grade coal.

### Kentucky Prices Weaken

Prices quoted on all coals mined in Kentucky are weaker this week than last week, due to unusually fine October weather, low consumption, heavy production, lack of interest by consumers and the fact that operators tried to ride the market up too fast when demand was good and they were a bit oversold. The high prices put out on future delivery quotations killed demand, and when orders in hand were filled operators had to accept lower priced business in order to keep running.

In eastern Kentucky screenings have held quite well, in spite of heavy production, and prices are 85c. @ \$1.05, but with very little tonnage over 95c. In western Kentucky the market has broken, as Illinois, Indiana and other fields have been offering cheap screenings, and forced the market, until some western Kentucky distressed stuff is said to be quoted as low as 50c.

The eastern and western Kentucky markets are closer together on quotations than for a long time.

Eastern Kentucky is running well, with very little car shortage reported, and a number of mines that have been idle are on the producing lists. It is claimed that the Hazard field probably will break production records in October, and the Harlan district also is producing a fine volume.

### Northwest Trade Sags

Official reports of stocks on Duluth docks Oct. 1 as given by the U. S. Engineer's office show less coal than on Sept. 15. This is due to the fact that dealers are stocking up and also because anthracite has been moving to some extent. The soft is 4,656,000 tons, of which 2,100,000 is free, and the hard is 610,400 tons. Shipments, however, are picking up. Thirty-six cargoes arrived last week, of which four were hard coal, and fourteen are en route, of which three are hard.

The feature of the market at the Head-of-the-Lakes is the heavy demand for Pocahontas lump, which is now selling at \$8, with every possibility of another 50c. jump at the first of the month. There is no change in run of pile or screenings. The accumulation of Pocahontas screenings is getting beyond a joke. Prices are unchanged on all coals. Industrial demand is at a standstill. The iron ranges are practically closed down waiting for the election results.

Anthracite has slacked off in the past week, but the stocks on docks were reduced nearly 60,000 tons in the last fifteen days before the first of the month. There will be no shortage of hard coal at Duluth-Superior.

Mild autumn weather has made the coal trade of Milwaukee a waiting game. Consumers are holding back until lower temperatures compel them to fill their bins, and dealers are waiting for the consumers. The pressure for Pocahontas has eased somewhat because of the recent advance in the face of prevalent mildness. Coal continues to come in freely by lake. Thus far in October Milwaukee has received 50,807 tons of anthracite and 159,007 tons of bituminous coal.

### West Is Fairly Busy

Warm weather and less demand have enabled operators, some of them as much as a month behind on orders for domestic grades, to catch up with their orders. A further cut in the price of screenings in all the Southwestern fields has reduced the surplus of this grade. Kansas screenings dropped 35c. down to \$2, Arkansas screenings from the circular price of \$2 to \$1.50 and Henryetta (Okla.) screenings, which have been \$2, are now \$1.50 @ \$1.75. There have been no other price changes.

A more favorable week was experienced in Colorado last week due to the growing demand for domestic coals. Mines averaged thirty-one hours last week with less than 20 per cent of the working time lost attributed to "no market." A number of operators are booked ahead for thirty days.

In Utah intermediate sizes and slack are moving easier. Mining and smelting companies and the railroads are the best industrial customers now. Prices are more settled than for a long time. Even the expected advance in the retail market is not likely to materialize.

### Mild Weather "Settles" Ohio Markets

The Cincinnati market has "settled" a little in the past week, more through the effect of the weather than a stoppage of buying orders. There is still a cry of shortage of equipment from the southeastern Kentucky and West Virginia fields, due mostly to the fact that numerous mines which have not worked for weeks or months are starting up. The movement continues at the peak with occasional reports that dealers have suspended or cancelled orders, due to the fact that there has come quite a spread once more between the asked price and "spot" prices.

A marked slackening in domestic orders at Columbus, due to mild weather, has permitted producers and shippers to get cleaned up and the market is now in a waiting attitude. Prices on a retail basis are still strong at the higher levels which have prevailed. Smokeless grades and splints are still in a fair demand, but southern Ohio business has fallen off. The expected increase in steam business has failed to materialize and the trade is waiting to see what happens. Contracting is quiet, and cheap coals, mostly demurrage cargoes, are often sold at bargains. Screenings are still very weak. Lake trade is going along as usual for the lateness of the season.

Moderate temperatures in eastern Ohio have done considerable to dampen the steam as well as the domestic trade, which has been especially active. Steam buying is on a hand-to-mouth basis, and requirements are more or less at a minimum, because industrial operations have not gotten back to normal by any means. There is no change in spot prices, which are holding firm and are not expected to recede because producers are limiting operations to ship-

ments on coal already sold, and little distress coal is reported.

Big output, low prices made from beyond the Pennsylvania line and mild weather are conspiring to prolong the slack condition of the Buffalo market, which approaching winter is not able to counteract. It is time, by the calendar, for demand to rise rapidly and the smaller stocks from those of the early part of the year also warrant such a stir, but consumption does not seem to warrant it. Demand is quiet and prices are weak.

Owing to the prolonged spell of mild weather the demand at Toronto is rather slack with prices as follows: Pennsylvania smokeless, \$5.85; steam lump, \$6.25@ \$6.75; slack, \$5.70. Anthracite is \$15.50, and supplies are plentiful.

### Pittsburgh Has Competitive Market

The Pittsburgh market is in a highly competitive position with too much production, the buying having fallen off. Operation has been at a 50 per cent level since the middle of September. Domestic coal is moving in fair volume, at former prices. A number of producers are pursuing the policy of not soliciting business, hoping that thereby the market will work upward to a reasonable level.

### Demand Picking Up in New England

For really high-grade run of mine New River and Pocahontas \$5.50 gross ton on cars Boston is now the general asking price for prompt and nearby shipments; business was closed during the week for shipments a fortnight hence at \$5.65. Prices have strengthened noticeably in the Providence market, no first quality steam coal being offered now under \$5.40 on cars and \$5.50 being asked not infrequently.

Local shippers who purchased pool 1 run of mine New River and Pocahontas early in the week at \$4.35 gross ton f.o.b. Hampton Roads are now unable to obtain anything under \$4.40, and even at this offerings are light. For the choicer coals \$4.50 is firmly quoted. Tonnage purchased at the former level of prices for New England shipments is now well cleaned up and shippers here are forecasting \$6 coal in New England before the year is out.

Demand is increasing considerably, particularly at Boston, and inquiries are becoming quite numerous. Both sales and inquiries involve some substantial blocks for spot, next sixty days and through to April 1. One sale of 10,000 tons of New River has been closed for shipments to April.

No worthwhile expansion is noted in all-rail coal but prices are a bit firmer, tonnage that has been offering at \$2 net ton mines being generally quoted \$2.10@ \$2.15, so the landed cost still favors coal from tide.

### Atlantic Markets Improve Slightly

No considerable improvement is reflected in the New York market nor can it be said that the situation is any quieter than it was last week. Line trade shows no increased activity, but the situation at tidewater has changed somewhat because of heavier shipments. Most of the coal sent here has been on contract and a little extra demand has practically cleared up the free coals. This has happened a few times recently, causing a slight price advance.

In the matter of tonnage the Philadelphia market is improving but prices continue on the old level. More coal is moving on contracts and prices for this business are considerably above spot quotations. Last week one of the utility plants in the city closed for 1,000,000 tons, divided among two producers. Everyone is hopeful that after election business will go forward much more rapidly. There

are very light holdings of coal at tide, and very few charters recorded recently.

The tide has turned at Baltimore in home trading for bituminous coal. There is no shortage of fuel, but purchasers are not quibbling when holders of better grade fuels ask 10c. to 20c. in advance of the recognized average prices of a few weeks ago. Despite the fact that the first 17 days of October have fallen behind the same period of September in coal exports there is an air of expectancy in shipping circles that is encouraging.

At Birmingham all grades of coal are suffering because of comparatively light demand. The weather is very dry and surplus domestic coal is moved with some difficulty. Prices are pretty well stabilized, with no likelihood of lower levels through the balance of the year. With the advent of cold weather both domestic and steam demand are expected to improve greatly. Production has risen materially.

### Anthracite Output Picks Up

From the viewpoint of the producer and shipper the anthracite market at New York is about all that could be expected so far as demand goes, but retail business is comparatively quiet. To induce buying while it is possible to get coal and avoid transportation troubles the aid of city officials has been solicited and appeals have been issued to consumers. Coal from the mines is easily moved. There is an urgent demand for stove with chestnut a close second. Egg is not so easily moved unless it is taken with stove, but it is not accumulating. Independent quotations for stove in straight lots are reported as high as \$11 but the average maximum is 50c. lower, and when taken with egg or chestnut sizes is quoted still lower. Pea is easy and in some instances hard to move alone. Demand for steam coals is steady, but prices, except for barley, are generally below company schedule.

Demand at Philadelphia is moderate because of the mild weather. Stove remains the only really active size, but chestnut is improving. Pea is moving slowly, even with curtailed production. There is only slight demand for egg, which seems to await colder weather. The retail trade is restive and the number of dealers cutting prices has increased. Steam coals are slow, and the only improvement is due to curtailed production. The mines are gradually resuming production after the flood, until at this time there are only a few that have not mined some coal.

At Baltimore the demand for hard coal continues to increase with the cooler weather. Most dealers have sufficient supplies on hand to meet this demand, except that some are short of stove coal. Many householders who have open fireplaces and who have been in the habit of burning logs until real cold weather sets in apparently intend to burn coal from the outset of cooler weather.

Trade at Buffalo is better than it was, but sunny weather has held back really brisk business. Sellers are somewhat uneasy, fearing car shortage and that supply will run below demand. The shippers who contracted to furnish the city schools most of their fuel in the form of Pennsylvania smokeless coal report that it is giving full satisfaction.

## Foreign Market And Export News

### Foreign Demand Gains in British Market; Prices Fairly Steady

With the exception of semi-anthracite, the demand in the Welsh coal market shows scarcely any improvement. Foreign demand is somewhat better with French and Argentine railways inquiring for larger quantities. Foreign bunkering depots also are taking heavier supplies. Some collieries where stoppage notices expired are now continuing operations from day to day.

There is an abundance of coal on hand, but operators have declared that they have gone to the limit in price concessions; in these circumstances prices have remained fairly steady. The position in the European coal markets makes business with France very difficult, while there is no trade with Belgium, owing to the industrial situation in that country. There is an almost total absence of inquiry from Holland and Germany. The rise in freights to South America has been a setback.

Operators in the north of England also have refused to make any further concessions in prices, so that the Newcastle market is given an appearance of firmness. There is very little trade at all; pits are still closing down, and nearly all of the rest are operating on short time.

Output by British collieries during the week ended Oct. 4, a cable to *Coal Age* states, was 5,155,000 tons, according to the official reports. This compares with 5,208,000 tons produced during the previous week.

#### Business at Hampton Roads Develops Strong Tone

The Hampton Roads market was considerably stronger this week due to shortage at the piers and a strong demand for bunkers, together with a pick-up in coastwise trade. Foreign business has shrunk, with little in sight.

Domestic business is weaker, on account of unusually mild weather. High-

volatile coal is less in demand, and its price was not changed during the week, the other pools going up materially. Business in pools 1 and 2 was brisk and the piers were busy. Accumulations at tidewater were reduced materially through rail shipments to the west direct from mines, and stronger prices were more attributable to this than to any extra demand.

#### French Industrial and House Coals More Active

While the situation in the French coal market shows no general improvement, orders for industrial coals have been coming in steadily since prices for October were established. The railways show hesitancy in buying French coals, the prices of which are considered too high in comparison with those of Germany and the United Kingdom. Demand is generally weak, with stocks about normal.

For house coals the demand is more active, but shipments are delayed through the rolling stock position. Deliveries of house coal from Belgium are slow, apparently having been reduced for the purpose of selling at higher rates when opportunity presents itself. Arrivals from Germany on the open market are not important.

Rail traffic is somewhat congested, especially on the State Railway lines; canal freight is quiet but steady at 23f. Béthune-Paris; 9-9. 25f. Rouen-Paris.

Reparation deliveries from Sept. 1 to 29 amounted to 895,765 tons of fuels, including 432,472 tons of coal, 423,030 tons of coke and 36,263 tons of lignite briquets; or a daily average of 30,700 tons.

On Oct. 1 the prices of industrial fuels on trucks French frontier, trucks or canal barges, French ports of the Rhine, were lowered by 2.50f. per ton. House coal and lignite briquets are

unchanged. Prices for oversea cargoes, via Rotterdam, Antwerp or Ghent, for French Channel, Atlantic or Mediterranean ports have been reduced 5f. per ton for unscreened 18-26 per cent volatile matter and washed steam peas. On trucks or canal barges, Antwerp or Ghent, prices are unaltered.

From Oct. 1 to 8, the O.R.C.A. received 77,693 tons of coke, a daily average of 9,700 tons. The price of reparation coke, unaltered thus far, probably will be changed soon.

The position of the Belgian coal market is critical and there are bitter complaints of severe competition. Boring mine owners having refused to arbitrate, the strike continues and is even growing worse.

## News Items From Field and Trade

### ALABAMA

The Munro-Warrior Coal Co. is considering the erection of a new tippie at its Nauvoo No. 2 mine, Walker County, and it is understood that plans for the structure are now being drawn. These mines are now operating on practically full time.

W. L. Smith and associates of Gadsden, are opening coal mines at Altoona which may soon be producing from 400 to 500 tons daily. They will turn out 200 tons at the start, it is stated, and the coal is of high quality. A tippie 65 ft. high is being completed and a spur track on the top of the mountain runs back to the opening, a distance of 2,300 ft. A new system of mining is being employed, which it is asserted will reduce the cost. The Underwood seam on the property is 4 ft. 6 in. thick. The Blue Gem seam also is to be worked.

Charles F. DeBardeleben, Jr., has been appointed general manager of the Alabama Fuel Co., with supervision over all properties, according to a recent announcement. Mr. DeBardeleben probably is the youngest man in the state to be given such a responsible position. His father is president of the company, which includes some of the largest and most active coal operations in the state. The new general manager, after coming from school, was sent to the Overton mine, where he was employed, and was later made superintendent of that plant.

Officials of the Sloss-Sheffield Steel & Iron Co. have practically completed negotiations for the purchase of the properties of the Alabama Company. The deal will give the Sloss-Sheffield company four furnaces in Etowah County and coal properties in Tuscaloosa County. Besides it will get possession of the Mary Lee mine near Birmingham, and of a small railroad which will enable the Sloss company to make connections between its furnaces and its coal mines. Use of this road is expected to save Sloss a substantial sum in freight charges annually. The price, including certain obligations to be assumed by the Sloss company, is approximately \$4,000,000. There will be no public financing.

### COLORADO

Ralph F. McKinley and Charles H. Cox, experienced in the Canon City and Crested Butte regions, have taken over the Butcherknife mine, 14 miles west of Steamboat Springs and expect to build a 2-mile branch from the Moffatt road to the mine. C. O. Rudisill, who has been operating the mine, has gone

into the feed and fuel business in Steamboat Springs.

### ILLINOIS

George A. Miller, who was Western manager of sales for the Sheridan Wyoming Coal Co., under Peabody Coal Co. management has been made general sales agent of the Peabody company with an office at the company's headquarters in Chicago. The contract for selling the Sheridan Wyoming Coal Co.'s output terminated Oct. 1.

Peabody, Houghteling & Co. are offering \$2,250,000, 7 per cent cumulative preferred stock of the Peabody Coal Co., of Chicago. This stock, part of an issue of \$4,425,000 already outstanding, was acquired by Peabody, Houghteling & Co. from certain of the stockholders at private sale and is offered at 100 and accrued dividend, to yield 7 per cent.

J. H. Evans, of St. Louis, has joined the clerical forces of the Old Ben Coal Corporation at Mine No. 12, near Christopher.

George Duncan, of Alton, was made permanent receiver for the St. Louis Coke & Iron Co., of Granite City, recently when the case was called for hearing before U. S. Judge Louis Fitzhenry at Springfield. Duncan was made temporary receiver a few weeks ago when a petition in bankruptcy was filed.

The Valier Coal Co., at Valier, broke its hoisting record recently by hoisting 7,072 tons of coal in eight hours. The output filled 125 railroad cars. The mine on that day averaged 1,000 tons per hour actual hoisting time.

Mine No. 5, at Pinckneyville, is the first Southern Gem Coal Corporation property to start operations since the general shutdown of the bankrupt company's mines late last December. The mine worked 5 days last week and prospects are good during the coming months for steady operation. While a full crew is not being employed, the larger portion of the former miners employed at the plant are again working.

### KENTUCKY

The East Kentucky Coal Co., of Hazard, has increased its capital stock from \$50,000 to \$100,000.

It is reported that coal operators and shippers of the Kentucky district are generally opposing the Howell-Barkley transportation bill, up before the last Congress and to come up again soon, and a number of large organizations have adopted resolutions con-

demning this bill, and also the proposed twentieth amendment to the Constitution, which would prohibit any work, even home work or farm work, for any boy or girl under 18 years of age. The latter bill would aid union labor alone and be of no advantage except to aid union labor in getting a higher wage scale and work a hardship on parents.

T. L. Bell has been appointed general superintendent of the Kentucky mining operations of the Munro-Warrior Coal & Coke Co., with headquarters at Nortonville. Mr. Bell was formerly attached to the engineering department of the Tennessee Coal, Iron & Railroad Co.

An involuntary petition in bankruptcy was filed in the U. S. District Court at Covington Oct. 11 by the Mahan Co., the Powell-Hackney Co. and the Hazard Fruit Co. against the Blackey Coal Co. of Blackey, seeking to have the defendant company declared bankrupt. The creditors' claims aggregate \$5,571.69.

R. C. Tway, head of the R. C. Tway Coal Co., Louisville, with mines in eastern Kentucky and retail yards in Louisville, has purchased at a reported price of \$60,000, 100 ft. of Broadway property, in Louisville, for enlargement of the coal and building supply business now on adjoining property.

There were fifty causes for the 11,572 accidents in Kentucky's greatest industry, coal mining, from Aug. 1, 1923, to Aug. 1, 1924. Falling objects netted 4,034 mishaps. Being caught between objects caused 3,325. Falls of coal, slate and shale caused 1,974. Other causes, bringing the total accidents to 11,572 were: Emery particles, dust 538; handling heavy objects, 338; sharp edges, 292; miscellaneous or unclassified, 135; coupling cars, 121; slipping, 120; hot metals, 83; nails stepped on, dump and pit cars, 76; hit by vehicles, cars, etc., 63; motor or hand cars, 56; electricity, 54; falls from wagons, cars, etc., 32; hit by machine parts, 31; powder and dynamite explosions, 27; hit by hoisted objects, 27; animal kicks, bites, 23; stumbling, 15; collision of cars, 15; hot substances, 13; hit by chips, etc., 22; hand tools, 10.

### NEW YORK

Justice Nichols of the New York Supreme Court has signed an order permanently restraining operations of the Cranston Coal Mining Corporation in New York State. Amos D. Moscrip, Deputy Attorney General, told the court that the firm's operations had cost residents of Wayne, Monroe and Genesee counties more than \$100,000 when they

answered advertisements and purchased stock in the corporation to obtain coal from "their own mines." Purchasers were taken to the mining district near Carbondale, Pa., and coal mines represented as belonging to the company were shown to them. Investigation showed, Mr. Moscrip testified, that no coal had been produced in Pennsylvania by the firm. Officers of the corporation were named as Robert McLaughlin of New York, president; William M. Day, of Norfolk, Va., vice-president, and E. M. Saunders, of Philadelphia, secretary and treasurer.

## OHIO

The Combined Coal Co., capitalized at \$42,000 has been organized at Crooksville by sixteen miners. They have taken over the Cres Mar Coal Co.'s holdings, and plan to supply domestic coal and also to ship a portion of their product. George Appleman is president; Harvey Smith, vice-president and Fred Reed, secretary-treasurer.

## PENNSYLVANIA

Business in the Connellsville coke region continues to increase gradually. At the Orient plant the Hillman Coal & Coke Co. is firing 180 ovens and the Oliver & Snyder Steel Co. is increasing coking operations.

The Buckeye Coal Co., Brownsville, Pa., a subsidiary of the Youngstown Sheet & Tube Co., expect to finish the installation of the skip hoist at the Nemacon mine in Greene County, about Jan. 1, after which daily output will be increased from 3,000 tons, as at present, to 5,000 tons.

After being in operation for 81 years the Coleraine mine, near Hazleton, has been closed down permanently. In its 81 years of operation the mine has had three different owners.

"Work at the Face" meetings, which are a form of educational and entertainment gatherings of mine workers and superintendents, were conducted last week by the Olyphant and Eddy Creek collieries of the Hudson Coal Co. in Olyphant. L. F. Weichel, new superintendent of collieries, addressed the meetings.

The Haddock Mining Co., aside from striking valuable and extensive virgin coal deposits in the vicinity of Silver Brook, where it recently acquired new

holdings, has struck some extensive veins of which nothing had been known in that section. It is thought that these are extensions of the different veins, the Mammoth included, from the Mahonoy Valley coal basin.

Boyd C. Osler, mining engineer for the Hazle Brook Coal Co., in Hazleton, has resigned to become chief engineer and general superintendent for the Shamokin Coal Co., a concern that was recently organized for the purpose of reopening the old Neilson mine, in the Shamokin field. At one time Mr. Osler was in the employ of the Susquehanna Coal Co.

A mine abandoned by the Lehigh Valley Coal Co. located in Pottsville more than 25 years ago is to be reopened at once by Scranton and Wilkes-Barre capitalists. At the time of the abandonment of the mine, known as York Farm colliery, Lehigh Valley officials predicted that it would be reopened. Some of the coal will be taken from under the Schuylkill County court house, where veins lie so close to the surface that coal is struck in digging cellars.

There has been so much idleness among miners in the Phillipsburg region of central Pennsylvania due to the operators being unable to compete with other fields that the children of miners have been obliged to remain out of school through lack of proper clothing and sufficient food. People of the town recently contributed to a fund to purchase clothing for the children.

Representatives of many anthracite companies recently were the guests in Hazleton of the Bucyrus Steam Shovel Co., of Bucyrus, Ohio, to inspect the first power shovel over the 80-ton limit used in the anthracite field and the operation of equipment by electricity, with standard gage locomotives and cars on standard gage tracks at the Cranberry Creek Coal Co. stripping operation. The 380-ton shovel used in the stripping operation is the largest in the anthracite region. Following the demonstrations the company was host at a dinner at the Altamont Hotel in the evening.

Sixty-nine of the 168 fatalities during September in the industries of Pennsylvania occurred in the coal mines. Thirty-eight of these deaths were in the anthracite and 31 in the bituminous mining districts. In industrial and manufacturing plants 65

fatalities happened during September while in the public utilities there were 34 deaths. The mine fatalities were divided as follows: Anthracite—Lackawanna, 8; Luzerne, 18; Northumberland, 4; Schuylkill, 8. Bituminous—Allegheny, 1; Armstrong, 1; Butler, 1; Cambria, 4; Clearfield, 1; Fayette, 7; Greene, 1; Indiana, 5; Somerset, 2; Washington, 3, and Westmoreland, 5.

Harrison D. Mason, Jr., formerly secretary and member of the firm with the Mine Safety Appliances Co., Pittsburgh, is now chief engineer with the Commercial Coal Mining Co. at Ebensburg. "Joe" Mason, as he is very generally known among his friends, is well known to the coal mining fraternity through his five years' service with the U. S. Bureau of Mines, as safety engineer attending some 38 mine explosions and fires, also through his service as secretary-treasurer for the Coal Mining Institute of America.

The present officers of District No. 2, United Mine Workers, which includes the central Pennsylvania bituminous field, will all have opposition at the election which will be held in December. District President John Brophy will be opposed by George Bassett, of South Fork, while Vice-President James Mark will be opposed by Jerre Ford, of Patton. John Ghizzoni, of Washaw, is having opposition in the person of Evan Thomas, of Barnsboro, for member of the International executive board. Richard Gilbert, the present secretary-treasurer, will have no opposition. Practically all the members of the district board and the organizers have opposition for reelection.

Three masked bandits, heavily armed and with a high powered automobile waiting to carry off the loot, held up a train crew and three guards early Saturday morning, Oct. 11, and carried off a safe containing \$33,000 in cash belonging to the Ebensburg Coal Co., intended to pay miners at the coal company's operations at Colver, Cambria County. James Garman, aged 65, employed as a guard by the coal company, was shot when he grappled with the bandits.

The Koontz Coal Co., of Frostburg, Md., announces the purchase of the Pine Hill Mine, in Somerset County, formerly operated by C. J. Rowe & Co., which went into the hands of receivers. Pine Hill is one of the oldest workings in the Somerset field and for many years produced a large tonnage. The Koontz Coal Co. was recently organized by William and James Jenkins, of Frostburg, and Jonathan Jenkins, of Baltimore.

Officials of the Cranberry Creek Coal Co. in the Hazleton field of the anthracite region are having a permanent flume constructed to carry the flow of mine water past a mine opening. It is of large capacity and will afford protection there against conditions which arose several weeks ago when a rain-storm swept the anthracite section, causing heavy damage to various operations. Cypress is being used and the wood is grooved to provide for any expansion. The side supports for the flume are now in place and the bottom

### Mabscott Team

This group scored a perfect record and won \$60 and the company cup in the New River Co.'s fifth annual first-aid contest recently at Mt. Hope, W. Va.

boarding also installed. The job is being watched with unusual interest by coal company officials generally.

## TEXAS

The Texas Gulf Sulphur Co., of New York City, is reported to have acquired 1,400 acres of lignite land in Milam County, Texas, and will develop same.

## VIRGINIA

J. H. Franks, of Toms Creek, has resigned his post as assistant superintendent and general mine foreman of the Virginia Iron, Coal & Coke Co., to accept a better position with the Fordson Coal Co.

## WYOMING

Production in the Rock Springs district is steadily improving. Most of the mines, with the exception of some of the smaller commercial producers, are working five days a week. On Oct. 2 the peak for the fall was reached, when approximately 15,000 tons was shipped.

Only two more bodies remained in the Sublet No. 5 mine of the Kemmerer Coal Company, on Oct. 8, four bodies having been recovered the day previous. These were found beneath bad cave-ins on the slopes. Thirty-nine men lost their lives in this mine on Sept. 16 in an explosion which badly wrecked the mine.

Eugene McAuliffe, president of the Union Pacific Coal Co., has offered the churches of Rock Springs full co-operation in obtaining church services for the outlying camps of the Rock Springs district. The ministers of that city are working out a schedule. It is thought that each denomination will name a Sunday night during the month when services will be held in a specified camp by its minister. Some churches also are preparing social service programs, chief of which is the Methodist, Rev. Roy E. Burt, pastor, who is planning week-day religious groups and boys' and girls' activity clubs for all camps.

Life checks are now in use in all of the mines of the Union Pacific Coal Co. at Rock Springs, Cumberland, Hanna, Winton, Superior and Reliance, it has been announced from the company headquarters at Rock Springs. Every person who enters a mine of this company, whether miner, official or visitor, receives a brass check bearing a number, and the name of the person together with the number is listed on the company books until the bearer has returned the check.

## CANADA

The congratulations of many friends are being extended to Gordon B. Mackie, of the Penn Canadian Fuel Co., Toronto, on his recent marriage at Stroud, Ont., to Miss Lucy McWaters, of that place.

Following a series of conferences held by Roy M. Wobvin, president of the British Empire Steel Corporation, and the steel and coal managers, H. J. McCann, general manager of the Dominion Coal Co., stated that conditions

at present do not warrant the expectation that more than two Cape Breton mines will be kept in operation during December and January. However, if efforts now being made to obtain a Canadian National Railways contract prove successful, the steel plant will re-open before the end of the year. Should this be the case there should be an average amount of employment at the mines in the early winter. The management of the coal company insists that it cannot find a market for its coal and is therefore compelled to suspend operations in the majority of its pits. Not having any funds in the exchequer it is stated that coal will not be banked during the coming winter.

Among the questions to be decided during the western visit of Charles Stewart, Dominion Minister of Mines, is the fate of the lignite briquet plant at Bienfait, Sask., in which the governments of Saskatchewan, Manitoba and Canada spent many thousands of dollars.

A new colliery is announced for the Nicola-Princeton district in the Tulameen Valley Coal Mines. This company is developing what is reported to be a promising field and is likely to be shipping this winter.

Wm. Roper has retired from the management of the East Wellington Coal Co. and has been succeeded by William Wilson, formerly overman at No. 1 Mine, Extension, B. C.

George S. Rice, of the U. S. Bureau of Mines, recently visited the Springhill collieries and the submarine mines in Cape Breton of the British Empire Steel Corporation. At the request of the company he made an inspection of the method of mining in the Allan shafts, with a view to offering some helpful suggestions for improvements.

William Sherman, president of District 18, United Mine Workers, announces that the striking miners of Alberta have ratified the new working agreement, submitted to them for a referendum vote.

On Sept. 30 the output of the collieries of the Dominion Coal Co., a subsidiary of the British Empire Steel Corporation, was 18,018 tons, the largest for a single day in nine years. The total output of coal for September was 273,374 tons, an increase over August of about 40,000 tons but slightly less than the output for September, 1923.

The plant and land at Port Stanley, Ont., of the Nukol Co., which has been in the hands of a receiver for some time, have been sold to two Toronto firms for \$2,500. The company purchased the plant for \$5,000 and in addition to installing much costly machinery, renovated it extensively. The value of the machinery alone, which is to be shipped to Toronto, is between \$15,000 and \$20,000.

Norman Harvey, formerly Deputy Minister of Railways for the Province of Alberta, is making a survey of the coal resources of western Canada with a view to making a report to the Vancouver Harbor Commissioner. The purpose of the latter is to ascertain the prospects of building up a greater coal

bunker trade through the port of Vancouver. Mr. Harvey recently was in consultation with Howard Stutchbury, trade commissioner, and coal operators of Alberta. Mr. Harvey is classifying the coals of the two provinces and estimating the present and future requirements for marine bunkering at the Pacific coast. He also will report on the development of coastwise and trans-Pacific business both in marine and domestic coals.

An order made at Osgood Hall, in Toronto, last week directs the winding up of the Rocky Mountain Collieries on the petition of the Brazeau Colliers, Ltd., creditors to the extent of \$289,849. The Rocky Mountain Collieries were incorporated in 1909 with a capital of \$1,000,000, to take over certain coal locations owned by the German Development Co. Sir William Mackenzie, it is stated, promoted the incorporation, being desirous of obtaining a half interest in the properties. The provisional directors, G. A. Ruel, A. J. Reid and A. J. Mitchell, disclaim any interest in the company and referred the petitioner to Mackenzie, Mann & Co., whom they represented.

## New Companies

**Northwest Coal & Iron Co., Ltd.**, has been incorporated to produce and deal in ores, metals and minerals, with head office at Toronto and a capital of \$1,000,000, by Julia J. Butterfield, Alan G. McDougall, Frederick H. Honeywell and others.

**The Ute Coal Co.** has been incorporated in Axial, Colo., by L. H. Pattison, R. W. Kilmer and S. G. Lehr.

**The Bear River Collieries Co.** has been incorporated in Denver, Colo., with a capital of \$1,000,000, by J. L. Jones, G. E. Fraker and W. Glauster.

**The Beach Fork Blue Gem Coal Co.** has been incorporated in Tazewell, Tenn., by G. M. Montgomery, John T. Rogers and M. R. Carr.

Among recently filed charters in Kentucky were the following: **Elliott & Day Coal Co.**, Pikeville, capital \$10,000. W. K. Elliott, P. W. Day and T. L. Day. **Gregory Branch Coal Co.**, Grays, \$50,000. J. T. Gray, Matyle Gray and H. E. Hubbard. **Dozier-Diamond Coal Corporation**, Madisonville, \$20,000; W. B. Dozier, Jesse Dimond and E. W. Dozier.

**The Citizens Coal Co.**, with a capital of \$22,000, has been formed by Isaac Jones, Thomas C. Walton, John C. Howell and others at Higbee, Mo., to own and operate a coal mine.

**The Canon United Coal Co.** has been incorporated in Canon City, Colo., with a capital stock of \$20,000 and 10,000 shares of no par value, by W. E. Prall, M. Lewis and C. Linkins.

**The Jericho Coal Co.** has been incorporated in Owensboro, Ky., with a capital stock of \$50,000, by W. Minter, 1751 Linden Street, Memphis, Tenn., B. D. Williams, Jr., and Dolph Woodruff both of Mannington, Ky.

**The W. D. Lacy Coal Co.** has been incorporated, with a capital stock of \$10,000, in Waco, Tex., by W. D. Lacy, F. L. Miller, 1211 Washington avenue, and others.

**The American Steel & Wire Co.**, a subsidiary of the United States Steel Corporation, has acquired the plants and other assets of the Cyclone Fence Co. The latter company is capitalized at \$1,500,000 and has plants at Cleveland, Waukegan, Fort Worth and Newark.

**The Piedmont Coal Co.**, of Dora, Ala., has been incorporated with a capital stock of \$18,000, all paid in. The incorporators are Mrs. C. S. Ramsay, of Birmingham, and W. W. and J. H. Bankhead, of Jasper, Ala. They will conduct a general coal-mining business.

## Traffic

### Approves Cancellation of Rates By Lehigh Valley

The Public Service Commission of New York has approved cancellation by the Lehigh Valley R.R. of commodity rates on coal (anthracite screenings and pea and buckwheat screened from prepared sizes), carloads, from Tift Farm (Buffalo) to Buffalo, Caledonia, Cheektowaga, East Buffalo, Niagara Falls and Suspension Bridge, effective Nov. 2, 1924, leaving no rates in effect for such service. Sup. No. 1 to P. S. C. No. A-289.

The commission has also approved the cancellation by the Lehigh Valley R.R. of tariff providing handling charges on anthracite coal screenings (including pea and buckwheat) made in dumping coal into vessels at Tift Farm (Buffalo) and North Fair Haven, viz.: picking up and loading into cars for reshipment over trestle or for rail movement; effective Nov. 2, 1924, leaving no rates in effect for such service. Sup. No. 1 to P. S. C. No. A-300.

### Hearing Announced on Change In Ohio Switching Rate

The Coal, Coke and Iron Ore Committee, Central Freight Association Territory, will hold a hearing in Room 606 Chamber of Commerce Building, Pittsburgh, Pa., Thursday, Oct. 30, 1924, at 10 a.m., Eastern standard time, on a contemplated change in the switching rates on coal, coal boulets and briquets, coke (except petroleum coke), coke breeze, coke dust and coke screenings, carloads, as shown in B. & O., C. & C. Series, I.C.C. 2,429, from the point of connection of the Baltimore & Ohio R.R. with the Pennsylvania R.R. at Martins Ferry, Ohio, to private sidings on the B. & O. within the switching limits of Martins Ferry, Ohio. It is proposed to cancel the switching rate of 13c. per net ton, minimum \$3.60 per car, and apply a rate of 76c. per net ton, as per Agent Davis' Tariff I.C.C. 43, and B. & O. Tariff I.C.C. 2,306.

### Hearing Set on Application for Through Rates from Colorado

Examiner Keeler of the Interstate Commerce Commission will hold a hearing at Topeka, Kan., Nov. 7, on the application of the Kansas Public Utilities Commission for a through rate on coal moving from Colorado to points on the Frisco and Katy.

"At present, points on these lines are paying a combination of local and through rates," A. M. Corp, rate expert for the Utilities Commission, explained. "A through rate to these cities would result in a considerable decrease. We desire to put into effect joint through rates and divisions on coal from Colorado in place of the present schedule, which is a combination of locals over the junction points."

The Santa Fe, Union Pacific, Missouri Pacific, and the Rock Island are the defendants in this action. All

these lines bring coal from Colorado. The Frisco and Katy do not run into Colorado.

### Protest by Burns Bros. Against Hard-Coal Rates Dismissed

Freight rates on anthracite, in carloads, from the Shamokin district of Pennsylvania to Elmira, N. Y., are not unreasonable, the Interstate Commerce Commission has ruled. It also finds no irregularity in the failure of the Lehigh Valley to absorb switching charges at Elmira. Therefore the commission has dismissed the complaint of Burns Bros., of New York, contending that charges for the detention of interstate shipments of coal, in cars constructively placed short of destination, are unreasonable.

### Enjoins Raise in Switching Rate

The Colorado State Public Utilities Commission on Oct. 10 forbade the Colorado & Southern R.R. to make any increase in the freight switching charges in Denver for a period of 120 days. The railroad recently filed a notice that it intended making an increase of 33½ per cent. The Victor-American Fuel Co. protested.

## Association Activities

After a useful existence of eight years, the Southern Ohio Coal Exchange, which had headquarters in Columbus, passed out of existence last week. The association was composed of operators in the southern Ohio field, including the Hocking Valley proper and Pomeroy. W. D. McKinney was its secretary and active head while James H. Pritchard was mining commissioner. The association sprang into existence in 1916, when it was believed that a closer association of producers in the southern Ohio field was necessary and Mr. McKinney was called to be its first secretary. He waged many successful fights for the rights of the operators of that field, including several successful freight rate controversies before the Interstate Commission and the Ohio Utilities Commission. Lack of funds caused by bad business in the field is the cause for the demise. Steps may be taken later on to revive the organization or to get operators in that field together for mutual benefit.

## Obituary

William P. Porter, aged 57, a retired coal operator of Vinton County, Ohio, died suddenly while at a gasoline filling station from heart trouble. He resided in Columbus for the past seven years and was prominent in Masonic circles. He leaves two sisters and a brother.

## Coming Meetings

**Illinois Mining Institute.** Annual meeting, Nov. 22, Elks Building, Springfield, Ill. Secretary, Martin Bolt, Springfield, Ill.

**American Society of Mechanical Engineers.** Annual meeting, Dec. 1-4, Engineering Societies Building, 29 West 39th St., New York City. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

**West Virginia Coal Mining Institute.** Annual meeting, Dec. 2-3, Welch, W. Va. Secretary, R. E. Sherwood, Charleston, W. Va.

**Coal Mining Institute of America.** Annual meeting, Dec. 3-5, Chamber of Commerce Bldg., Pittsburgh, Pa. Secretary, H. D. Mason, Jr., Box 604, Ebensburg, Pa.

**West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers.** Fourth annual convention, Dec. 12 and 13, Huntington, W. Va. Secretary-Treasurer, Herbert Smith, Huntington, W. Va.

## New Equipment

### Lock for Electric-Light Bulbs

A simple and effective lock to prevent the theft of electric light bulbs recently was placed on the market by the Ren Manufacturing Co., Lyseum Building, Winchester, Mass.

This device, called the Ren-Lock, con-

Unlocked and Locked Lamp

The small size of the locking device permits its use on any brass socket regardless of the type of reflector used with the lamp. This feature is important if the light center is to be maintained.

sists of a coiled spring and a grooved ring. A special device is used to attach the lock to the socket.

When a lamp is locked in place by means of this device it cannot be re-

Spring and Washer

These are the only two parts of the locking device. The coiled spring has a projecting end which locks the lamp.

moved except by breaking the glass. A special bag is provided for catching the broken pieces.

### Straight Line Two-Stage Air Compressor

The low power consumption per cubic foot of air delivered and the favorable physical conditions of the air resulting from two-stage compression have long been recognized by compressed-air users, but the initial cost of the compressor and the expense of installation have heretofore overbalanced these favorable features, with the result that only machines of large capacity have been available—the majority of which have been of the duplex construction.

Such construction, while entirely logi-

**Two-Stage Compressor Arranged for Belt or Motor Drive**

This tandem unit is arranged so that all the stuffing boxes are easily accessible. The intercooler is rigidly mounted above the two cylinders and may be reached from either end. Automatic start and stop control apparatus, together with automatic unloading features, makes it easy to start or stop the compressor from remote points.

cal for machines of over 500 cu.ft. piston displacement, has proved too expensive to manufacture for smaller capacities, besides being too costly to install because of the complicated foundation required and the nicety called for in aligning the machine. Furthermore, the average compressed-air user has in the past neglected to look carefully into the power costs involved in operating single-stage air compressors of smaller capacities. Now, however, the economies required by present highly competitive business conditions make it necessary that every operating cost be reduced to the minimum, particularly power costs.

In order to meet the conditions outlined above, the Chicago pneumatic straight-line two-stage belt- or motor-driven air compressor has been developed. Operating at 275 r.p.m., this compressor has a piston displacement of 360 cu.ft. of free air per minute; air pressures range up to 125 lb. It is adapted to be driven by a belt or by a synchronous motor with rotor mounted directly on the compressor crankshaft.

Tandem construction is used in this unit, in which the low-pressure cylinder is placed next to the frame and the high-pressure cylinder is connected to the low-pressure cylinder by means of a tandem piece through which the piston-rod stuffing boxes are easily accessible. The intercooler is rigidly mounted above the two cylinders, in which location it is convenient for cleaning, which may be done from either end.

The whole unit is mounted upon a substantial subbase which gives the rigidity so desirable in a machine of this class. Perfect alignment of the machine is assured, resulting in maintained high mechanical efficiency and consequently prolonged life. This feature also gives the unit a degree of portability not realized in duplex construction and for this reason it will appeal to those compressed-air users who frequently employ semi-permanent installations.

On first thought it might appear that the bearing pressures in such tandem construction are unusually high, but such is not the case, as the maximum

pressures are even lower than those found in single-stage machines of equal size.

The whole unit is remarkable for its accessibility and ease of adjustment. The bearings are readily gotten at and adjusted with a minimum of exertion; especially is this true of the wedge adjusted connecting-rod bearings, which are so easily and conveniently adjusted that the operator is encouraged to keep them in perfect condition, thereby eliminating the most frequent cause of compressor failures.

Simple air valves are used throughout, assuring high efficiency and trouble-proof operation of the most vital part of the compressor.

Automatic operation is attained in a high degree. Splash and flood system of lubrication is employed for all bearings and the cylinders may be lubricated by the standard sight-feed lubricator, by a pneumatically operated force-feed lubricator, or by a mechanically driven force-feed lubricator.

Regulation of the volume of air and its pressure is entirely automatic and can be made to conform to the special conditions of the demand for air. Three-step capacity regulation is furnished in which two differential unloaders operating automatic unloading simple inlet valves cause the compressor to operate at full, half and no load, according to the air demand, with maximum efficiency and evenly distributed crankshaft torque. Such operation results in splendid load characteristics for the driving

motor since the steps are clearly defined in loading and unloading, obviating any surges in the power line that would otherwise result.

When the air demand is fairly constant for periods in the day, with intervening periods in which there is slight or no demand for air, and the compressor is driven by an electric motor, automatic start and stop control operation can be employed, in which case the unit is equipped with a centrifugal unloader which causes the automatic unloading inlet valves to be held open during the period in which the compressor is at a standstill and to remain open until, in starting again, the compressor has nearly reached normal speed, when the valves are again allowed to operate.

During slowing down prior to stopping, the unloader comes into action, throwing the load off the compressor, thereby eliminating much objectionable slapping of the belt in the case of a belt-driven unit. Complete automatic operation of the unit with utmost economy is effected through the use of a water-control valve which automatically stops the flow of cooling water through the jackets and intercooler during periods in which the compressor is at a standstill and allows it to flow when the compressor is in operation.

### High-Speed Motor Operates This Grinding Wheel

Forbes & Meyer, 192 Union St., Worcester, Mass., has developed a new grinder. The motor is of the induction type, giving speeds of 5,400 or 7,200 on 60-cycle three-phase current. Such speeds have generally been considered impossible with the induction type of motor, but have been accomplished by using two primary windings, each receiving current directly from the line, while both act on a common secondary member. The motor is fully inclosed.

The grinding wheel is mounted directly on the motor shaft. It is supported by three ball bearings, one close to the wheel, and one at each side of the motor. This makes the machine run smoother than it would if it were attempted to support as long a shaft as this on two bearings. The wheel is spaced 7 in. from the motor so as to avoid interference.

The 5,400 speed of the motor is correct for 4-in. to 4½-in. diameter wheels, and 7,200 is the speed for wheels of about 3 in. in diameter, though smaller wheels can be used efficiently.

#### Grinder and Motor on Same Shaft

Three ball bearings permit the grinder to operate efficiently. A specially designed high-speed motor drives the small wheel at 7,200 r.p.m.

## Keep Up With Progress

**E**LECTRICAL failures, like mine fires, often arise from neglect or ignorance. Many times common sense dictates that certain changes be made in electrical equipment. If these are neglected disaster is likely to follow.

In the early development and application of electrical apparatus many installations were made in a way which today appear crude and unsafe. This was quite natural; it was pioneering work. Our forefathers didn't go West in aeroplanes or even automobiles and not all of them traveled in covered wagons.

Procrastination or lack of respect for the opinion of an electrical engineer nearly caused a serious mine fire recently in one of the largest anthracite mines. It appears that inside this mine, some few years ago, several circuit breakers were installed in an asbestos-lined wooden box. The engineer had lately recommended that the breakers be inclosed in separate steel cabinets but the necessary appropriation never came. One night something went wrong with one of the breakers and all were destroyed and a mine fire narrowly averted.

It is apparent that the loss of the breakers and the delay to the mine was much greater than the cost of a safe cabinet. Mine fires are indirect causes of high operating expense and increases in the price of anthracite. Mine managers should learn to appreciate the judgment of the electrical engineer and cease to look upon him as a necessary evil and a spender of profits.

## Overloading Locomotives

**E**FFICIENCY in operation is promoted by attaching only reasonable loads to electric locomotives. The tendency is to load them down with all they can be made to haul, but certainty of operation is usually more important than maximum tractive effort. The railroads are learning this, with the result that the number of train miles has been greatly increased. A bucking locomotive holds up operation lamentably. It may come through with its trip but with what delays and what dangers. As to the latter it may be said that a trip that is too heavy is usually as greatly lacking in braking power as in tractive effort and so is liable to run away on grades.

When too much is demanded of a locomotive the motors may be burned or the locomotive may tie up machines by its excessive draft on the current strength. It may kick out the circuit breaker. Excessive use of sand may insulate its wheels from the rails and cause the current to run back along the cars. It may interpose an excessive resistance. Instead of bragging as to how much "she" can haul it is better to have a certain maximum load and not exceed it. A fine performance may be obtained at an entirely undue expense. A locomotive should be kept pulling its normal load, running according to schedule without drawing too heavily on the current and without heating.

Consistent running is what is needed. If a larger output is wanted add another locomotive, replace the present machine by one that is larger, ease the heavier grades or introduce anti-friction bearing cars, but do not overload the locomotive. That is the poorest kind of economy and may actually reduce tonnage by crippling the overloaded locomotive, so that it will not haul even a normal load.

## Harrington and the Flame Safety Lamp

**W**E CANNOT join with Harrington in his wholesale condemnation of the flame safety lamp. He records, of course, the accidents it has caused and not the accidents it has prevented. He could do no other, if he so desired. Yet we feel that in the article that appears in this week's issue he has done the public a service.

The flame safety lamp when carried with an electric lamp is not so likely to be tampered with as when carried alone, for the man carrying it can proceed rapidly and safely to the relighting station if it should be extinguished. The readiness with which the flame lamp is put out is one of its most undesirable characteristics especially because of the natural desire of the user to relight it at the earliest possible moment. Unfortunately, an electric lamp gives such a brilliant light, that unless it is kept away from the eyes of the user he is not able with his pupils thus dilated to read the faint blue flame of the safety lamp with exactitude.

Some carry flashlights, but these lamps might cause an explosion if the bulb were broken. There are doubtless other defects. These might be corrected, but so far that has not been done at least in the United States. It would be well if the defects were removed, then the man who tested for gas could do it with precision and yet would have the flashlight to guide him into safety if the flame safety lamp failed.

However, men are constitutionally averse to labor and others are only too anxious to perform their allotted task. In either case they are apt to take a chance and to open their safety lamps in order to relight them. A safe relighting device would be a blessing, but unfortunately a lamp soon fills with an explosive mixture if in a gassy place.

When the lamp is relighted unless the device for relighting acts instantaneously and automatically, as it does in one form of mine lamp, it causes an explosion within the gauze which may be violent enough to ignite the gas surrounding the lamp. All these are reasons why the flame safety lamp is not safe but at present only the Burrell testing equipment is available, and it is said to be slower and less readily understood though far more accurate than the flame safety lamp. No wonder inventors are hard at work in Europe to produce methanometers that will be simple and continuously reliable.

Where shotfiring is done by electricity and by specially appointed men, and where miners are prevented

from smuggling powder and fuse into the mine, there is little risk that the miner will open his safety lamp to fire a fuse, though miners have been known to shoot down coal surreptitiously rather than be deprived of their day's shift when a shot has missed fire or failed to bring down the coal.

The operator should either arrange for testing by the Burrell method or should contrive in every way to prevent all contingencies that would make the opening of a safety lamp in a questionable place seem desirable to the foreman, fireboss, shotboss or other mine worker. Furthermore, he should use judgment in selecting his lampmen so that the lamps will be always in repair, safe in themselves and properly assembled. And again, he should render his mine so safe by adequate rock-dusting that any explosion would be limited closely to the area occupied by the explosive mixture of gas and air, assuming, what has not been proved, that inert dust has no power to extinguish an explosion that is solely of gas and not of coal dust and possibly a little methane.

### Face the Facts

FOR YEARS we have proceeded with the notion that the mine foreman knew, or could know, enough to assure the safety of his mine. Now we are clearly convinced that unless we have an entirely new crop of foremen we cannot expect any such competence. Where such foremen are to be found no one knows. They would need to be electricians as well as mining experts, and few qualify in that direction. The mine foreman under the law is in control of the electrician. If the former is wise he leaves the electrician quite largely alone relying on him with his superior, the electrical engineer, to keep the wiring and bonding safe and insisting only that he does not violate the elementary principles of mine safety.

Unfortunately the foreman too often condones practices with regard to electrical apparatus, that do not make for safety, economy or efficiency. He does not know when machinery is properly protected. He does not condemn equipment that is in dangerous condition. He overloads motors and locomotives. He demands short and unsafe cuts. He means well but he does not understand electric current. We do not like to recommend two heads in a mine who may jangle and waste their effort in mutual incriminations. Still we believe the mine electrician should be certified and have charge of certain equipment with full responsibility for its safe keeping.

We think state mine inspectors should be trained to examine electric machinery in a competent manner. The department should have an inspector to train them and occasionally go from mine to mine with them showing them just what they should watch. Electrical hazards are real. They do not all end in electric shock. Overloading a locomotive may cause a runaway. Faulty upkeep of a fan motor may end in an explosion. The flashing of a defective rheostat may have a like effect. A short circuit may cause a mine fire. A defective battery may burn the man carrying it. A stray current from a locomotive or a stationary motor may cause a premature shot. Consequently many accidents now classified as non-electrical may have an electrical origin or at least a cause that a competent electrical engineer should of all men be the most able to remove.

Let us face the facts. The mine foreman cannot be

a competent electrician and he should relinquish to the latter all responsibility for the correct installation and manipulation of electrical equipment.

### His Life for Labor

ROBERT SMILLIE, the protagonist of the mine worker, has written his book "My Life for Labor," and his story of his early life as reviewed by a New York newspaper seems centered about wrongs in mining life that all the years he has spent in labor unionism have not removed—poor lighting, dangerous roof and falling water.

As for the lighting which might have been greatly benefited and is being improved, the union has done nothing except by opposition. One of these days we shall have mines that are well illuminated, but the way will be shown by the operator. The mine worker is content. He has struck against the electric mine lamp, and when stationary lamps have been installed to light his working place he has stolen the bulbs. But lighting, somewhat satisfactory lighting, is coming. No one can blame the operators of Smillie's youth that they did not have anything but a flame lamp to light his working place.

And as for the roof that nearly ended his career while a mere stripling, it is much the same menace it ever was. Labor unions have done little but sustain the miner in doing just as Smillie did. He left the roof unpropped and it fell, fifteen-hundredweight of it on a pile of "dross" (undercuttings) he had scraped for a seat from which to extend his undercut.

The roof still drips in shallow mines and in some deep ones. Unionism has done and can do nothing for it. It is inherent in mining and cannot be avoided. Fortunately it does not seem to have proved particularly harmful to health.

But the condition of the miner, nevertheless, has improved. We cannot blame the British operator of sixty years ago because he did not give his employee all the labor-saving equipment he provides today. Most of it was not so much as known in those days. Smillie would give little credit to invention and capital and a great deal to unionism, but one can well question if the first two have not been the workingman's friend and the third an extremely doubtful supporter.

Unionism has nearly always been against labor-easing devices, the mechanisms that lay on the machine the labor and burden of the day. But when the machine is established how cheerfully and successfully does the labor agitator proceed to lay his hand on the sacred pages of history and say that it is unionism and the social struggle that has lightened the burden of the worker. Smillie's book would appear thus to distort history, twisting it ever to suit his purpose.

His life for labor, what has it effected? Much we fear that it has produced nothing but the bitter fruits of high-cost coal for the workingman, high cost of living for the laborer, discontent and social unrest, whereas the work of the inventor and of the practical industrialist has lightened toil, made possible shorter hours and put a premium on the mind rather than on the limbs of the worker. The technical man is not invited to be Minister of two Governments as Robert Smillie has been, but none the less he does more effectually than labor agitators and politicians what governments, if they are good governments, seek to accomplish, but often alas in vain.

Drilling a Sheared Face

# Vertical Shearing Saves Powder But Makes Slack

Utah Fuel Co. Does Not Adopt It After Exhaustive Tests—Center Shear Cut Is Tried with Both Top and Bottom Cuts in Narrow Work and Rooms

BY E. W. DAVIDSON  
Associate Editor, *Coal Age*, Chicago, Ill.

IS VERTICAL cutting in rooms and entries economical? A good many coal mining men have asked themselves this question. Some have tried to find out by experience. T. A. Stroup, superintendent of the Clear Creek mines of the Utah Fuel Co., after exhaustive tests has concluded that, so far as the brittle Clear Creek coal is concerned, vertical cutting loses more money than it saves. The tests showed that vertical cutting is less expensive than horizontal and that a center shearing cut down through a face that has been top or bottom cut reduces powder cost per ton more than 50 per cent, but the percentage of slack produced in places only 12 to 14 ft. wide is more than doubled and is greatly increased even in full-width rooms. Thus the good effect is nullified. So vertical cutting is not standard practice in Clear Creek.

The 90-day tests which Mr. Stroup ran amassed a wealth of data on vertical cutting such as has been hard to find in the past in the coal industry. So it is of value. Some of the tests were run in entry work in No. 3 mine of the Clear Creek group where entries were supposed to be 12 ft. wide; there was so much overrunning of machines, however, that much of the work was fully 14 ft. in width and the results thus were somewhat comparable to those that might be gotten in room work. Other tests were in 18- and 20-ft. rooms. The studies included top cutting alone, bottom cutting alone and vertical center shearing in combination with either one or the other. Comparisons were made of the

time consumed in cutting, the quantity of explosives used and the proportions of slack produced by the cutting process alone and by both cutting and shooting. After a place had been shot it was loaded out with 1½-in. coke forks. Everything that went through the forks was weighed separately as slack.

The machines used in Mr. Stroup's tests were an Oldroyd universal cutter, a Goodman straight face machine and a Jeffrey 35-B shortwall. Comparative runs were made with these machines but the results were not intended to illustrate the relative merits of the machines but are held to apply only to the methods.

A general summary of important results showed that

NOTE—The illustration forming the headpiece shows the arrangement of shots employed to bring down a face that has been undercut and sheared, with the fewest and lightest charges. Much big coal was produced by this method but the large amount of bugdust made by the machines offset all advantages gained.

### Self Condemned

In passages 12 to 14 ft. wide center shearing nearly doubled the quantity of bugdust made by the machines as may be judged by the great pile of this material in the foreground. In wider work the proportion of cuttings was not so large but enough to render the process of vertical cutting uneconomical.

in places top cut and center sheared by the shearing machine, the cutting time per ton averaged 1.39 minutes, slack produced by cutting averaged 11.8 per cent, total slack from cutting and shooting averaged 27.3 per cent and powder cost per ton averaged 3.91c. Places merely top cut by the straightface machine gave the following results: Cutting time per ton, 1.10 minutes; slack made by cutting, 6.64 per cent; total slack made by cutting and shooting, 13.17 per cent (excluding results from one place which was badly overshot); powder cost per ton, 9.2c. Thus it is shown that powder costs per ton in places center sheared and top

Arrangement of Cuts and Shot Holes

It will be observed that center shearing a place that has been either undercut or overcut eliminates the necessity for one shot hole. Because of vibration of the cutter bar when making the shear this kerf is appreciably wider than those either above or below the coal.

Table V—Time Consumed in Cutting Places

All Places Bottom Cut and Center Sheared by Shearing Machine							
Room	Width, Ft.	Height, Ft.	Depth, Ft.	Time Cutting, Min.	Time Shearing, Min.	Time Total, Min.	Tons per Place

3	18	6	5½	36	26.53	1.4

cut and center sheared places required an average of 1.2 minutes of cutting time, per ton, they produced 11.6 per cent of slack from cutting alone and a total of 25.3 per cent of slack from both cutting and shooting, the cost for powder was 2.41c. per ton of coal produced. Places merely bottom cut averaged 1.4 minutes of cutting time, per ton, produced 8 per cent slack from cutting alone and 29.83 per cent of slack from cutting and shooting, while powder costs were 5c. per ton. Thus again, the expense incurred for powder was reduced more than 50 per cent by center shearing.

One explanation for the excessive amount of slack made by the shearing machine is that vertical cuts invariably have a kerf almost half again as wide as those made horizontally. Mr. Stroup says his experi-

Table VI—Slack Produced by Cutting Operation

ence was that a vertical cut, starting from the top, could always be made quickly because of the weight of the cutterbar acting in a downward direction, but that the bar was certain to vibrate considerably, thus making a wide gash in the coal. A cutter that ordinarily would make a 6-in. horizontal kerf usually made a 9-in. kerf in a vertical cut.

“The reduction in powder consumption was outstanding in all the tests,” said Mr. Stroup, in a report that was written for presentation before but which was never read at any meeting of the Rocky Mountain Coal Mining Institute. “So marked has this saving been that I venture to predict that if vertical cutting as an ad-

3	26.53	5	1.25	.18	.04½

junct to horizontal cutting is ever widely adopted it will be to bring about economy in explosives.

“The use of the vertical cutting method either alone or in conjunction with horizontal cuts for the usual room and entry work being thus disposed of the question of utilizing this method for drawing pillars was considered. It was hoped to cut pillars that were too heavy for horizontal cutting by a method of crosscutting and then drawing the stump; but the great length of the shearing machine made it necessary to do much of the cutting on the curve leading into the place.”

Shot Down

This shows the results of good shooting in a room that had been undercut and center sheared. As may be seen much big lump coal was produced. What cannot be seen, however, is the proportion of fine cuttings made by the machine.

# Flame Safety Lamp Proves Source of Danger

Several Explosions Caused by Safety Lamps Briefly Reviewed —  
Such Lamps Cannot Be Trusted Even in Hands of Certified  
Officials—They Should Never Be Used When a Shift Is at Work

BY D. HARRINGTON  
Salt Lake City, Utah

**"F**AMILIARITY breeds contempt" is a saying which certainly should not apply to anything so dangerous as explosive gas in coal mines, yet actual occurrences seem to prove that either contempt or carelessness is all too frequently found in present-day practices with respect to methane in mines, and particularly is this true as to the use of safety lamps. In three of our western states, ignition of methane from modern flame safety lamps in the hands of fireboss or safety man has resulted in six disasters, the death of practically 500 men and financial loss of considerably over \$2,000,000. In each instance the careless person causing the ignition lost his life. Four of these explosions with a total death toll of 412 took place within the past seven years.

In each of these disasters caused by gas ignition from flame safety lamps, the user of the lamp held a certificate of competency as a fireboss, a gas examiner or a mine foreman, and in at least three of the six cases, had a certificate of competency and experience in Great Britain as well as in the United States.

In two cases resulting in 220 deaths, the flame safety lamp was taken apart by the fireboss in the mine, and the gas ignition was caused when an ordinary match was being used to relight it. The burnt match in both cases was found near the disassembled lamp.

In at least two cases the safety lamps were modern and up-to-date and although provided with safety igniters or relighters and although these relighters were in place, they were not in condition to use. In one of these two cases the lamp was of the key-locked type; in the other it was magnetically locked. In both instances the mines were operated with closed lights, the miners using electric safety lamps, and the inspectors or safety men carrying flame safety lamps.

In two of these six disasters, the ignition was caused by improperly assembled safety lamps and in one case by a misuse of an apparently well-assembled lamp. In all six instances, the disaster occurred while an attempt was being made to remove gas accumulations during a working shift. In no case was the Davy lamp involved and in four out of the six instances the mine was operating with closed lights.

These six comparatively recent disasters in three states caused by methane ignition by flame safety lamps in the hands of men holding certificates of competency, leads one to doubt whether the designation flame *safety* lamp is not a misnomer. If they are not safe in the hands of the foreman, fireboss or safety man possessing a certificate of competency in their use, how can they be considered safe in the hands of miners not one in ten of whom has even a faint idea as to the tests to which a flame safety lamp should be subjected to determine its actual safeness and only a few of whom know the lamp's limitations or the correct methods of using it?

## DETHRONING THE FLAME SAFETY LAMP

**A**FTER a long and intimate acquaintance with coal mines, especially those in the Rocky Mountain region, where he served as an engineer for the Bureau of Mines, the author of this article has come to distrust all flame safety lamps when used for any purpose other than gas testing. He states that they started the Hastings explosion in Colorado in 1917, when 121 men lost their lives, the Kemmerer explosion in Wyoming in 1923 that killed 99, and the Castle Gate disaster last March which sent 172 miners to Kingdom Come; to say nothing of the hundreds of thousands of dollars of property loss that these explosions caused the mining companies. He for one, is "not at all inclined to place the safety lamp on an altar and worship it as so many coal-mining men are inclined to do." He sounds a distinct warning concerning the danger of these lamps.

It seems to be anything but safe to place any kind of flame safety lamp in the hands of the miner and I am particularly opposed to the practice of relying upon the machine runner in "slightly" gaseous mines to inspect working places for gas with a flame safety lamp before operating the electrically driven coal-cutting machines.

The disasters mentioned are only a few of those that have been started by flame safety lamps, and they are instanced here only because I happen to be personally familiar with the surrounding circumstances. Doubtless there have been numerous others.

In any event there have been many cases in which the users of the flame safety lamps have been burned. Furthermore, I have had called to my attention many practices likely to result in disaster. Among the most dangerous are the various methods used with flame safety lamps to "spit" fuse or squibs. Any place that is sufficiently gaseous to require closed lights is too gaseous for the safe use of fuse or squibs in blasting. If fuse or squibs are not in themselves dangerous, the methods employed in igniting them are likely to be decidedly dangerous.

As it appears to be fairly well established that ignition of methane starts nearly three-fourths of our coal-mine explosions, it seems only sensible that in any mine where methane occurs nothing but closed lights should be used. And in view of the danger incurred from flame safety lamps and the little light they give, I am convinced of the advisability of using only permissible electric lamps in mines that give off methane. This is particularly the case as it is claimed that the

newer types of permissible electric cap lamps will give as much light as carbide lamps.

A mine that has encountered no explosive gas in many years of work may overnight become definitely gaseous. This has actually occurred in more than one instance. This situation, together with the fact that open lights have started many fires in both gaseous and non-gaseous mines and have caused dust ignition both in mines and on tipples, leads me to the belief that open lights should be excluded from non-gaseous coal mines as well as those known to make methane.

In fact, up-to-date thought tends towards exclusion of open lights from *all* mines, including metal mines. Several large metal-mining companies are now experimenting upon the use of up-to-date electric safety lamps in their operations. Furthermore, the State of Utah requires the use of closed lights in non-gaseous as well as in gaseous mines.

#### CLOSED LIGHTS ALONE DO NOT GUARANTEE SAFETY

However, when the mine is placed on a closed-light basis, it is absolutely essential that other precautionary measures be not neglected. It is inconsistent, to say the least, to employ closed lights yet simultaneously have in use near working faces non-permissible electric coal-cutting machines, electric pumps, booster fans or other flame-producing electrical equipment. It is certainly not safe to allow smoking in a closed-lamp mine, to fail to make frequent search for matches or to fail to severely punish anyone taking matches or smoking materials into such a mine. Similarly it seems decidedly dangerous to blast during a shift in a closed-lamp mine, particularly if the blasting is done with fuse or squibs and black powder, and more especially if the coal is shot off the solid.

Standing gas should not be moved while men are on shift. This is true even if only closed lights are in use.

As far as possible, flame safety lamps should be excluded from mines when employed for anything other than inspection purposes, and even then they should be entrusted only to qualified men. Without exception they should be of the permissible, magnetically-locked type equipped with relighters, and any person, who for any reason whatsoever, takes a flame safety lamp apart underground, except in stations designated especially for the relighting of lamps, should be given the extreme penalty of the law. And this penalty should be made as severe as for attempted wholesale murder.

#### FLAME SAFETY LAMP AROUSES SUSPICION

I have examined a large number of mines after explosions and in almost every one, the inquiry was made (not always by me) as to the whereabouts of mine foreman, fireboss or safety man, and particularly as to where the flame safety lamp was found and what was its condition. This indicates the widespread suspicion directed towards the flame safety lamp.

A state mine inspector informed me that upon examination of records as to mine explosions in his state, it was found that 80 per cent were started by the mine officials (superintendent, foreman, fireboss, safety inspector) and that a large part of the disasters were caused by handling gas (usually with the shift in the mine) and in several instances a flame safety lamp caused the ignition.

It seems definitely dangerous to permit firebosses to examine old workings (where it is extremely probable

explosive gas may be found) while the shift is in the mine; yet this is the common practice.

Though the magnetically locked permissible flame safety lamp is recommended for use where lamps of this general type must be employed, many old timers refuse to change over from the lamp they have used for years and even when they do change over, they are prone to "re-make" the permissible lamps in accordance with their own ideas. When the relighters become worn and cause a little trouble, they are discarded or removed and the hole plugged. In one instance the relighter was removed and the hole left open with a resultant ignition of gas.

#### GAUZE REMOVED TO QUICKEN LAMP ACTION

One old-time fireboss thought two gauzes made the lamp "slow"; so one gauze was removed. Gaskets have been omitted entirely or defective ones used. I recently saw a modern up-to-date flame safety lamp taken into a mine for gas testing, and the glass cylinder had a V-shaped nick extending down more than a quarter of an inch. Fortunately no gas was encountered.

Firebosses at times remove the locking devices from permissible flame safety lamps. Others drill a tiny hole in such manner that the insertion of a pin opens the lamp. Some claim to be able to open the magnetically locked permissible lamps at underground trolley frogs and others by subjecting the lamps to a certain method of jarring.

So long as this attitude toward permissible flame safety lamps is taken by officials on whom depends the safety of the mine and its workers, there doesn't appear to be any definite guarantee that the permissible lamps will be much safer than the Davy. At any rate, the fireboss, foreman, or other person taking a flame safety lamp into a mine, while a shift is in, should be compelled to test the lighted lamp before going into the workings in an explosive gas mixture by hanging it free in a gas-testing box. Furthermore, any certificated man using a flame safety lamp in a mine in which a shift is at work and having matches or smoking materials in his possession should have his certificate revoked and be prosecuted under the law, provided the statute carries any penalty for such an offence.

#### FLAME SAFETY LAMP IS NOT FOOLPROOF

There is decidedly too much tendency to assume that the flame safety lamp is foolproof. In recent years I have felt uncomfortable when in a gaseous mine where a number of flame safety lamps are in continuous use even when so-called certificated men are using them. It seems desirable not only that all users of flame safety lamps should be cautious and careful but it also seems advisable to exclude as far as possible, *all* flame safety lamps from closed-lamp mines, or in fact from all mines, when the shift is working.

The Burrell methane detector is much more accurate in detecting gas than is the flame safety lamp and while more time is required per test, there is absolutely no reason why this or some similar instrument should not be used for gas testing in mines when the shift is at work, reserving the flame safety lamp for the fireboss' examinations before the shift comes on.

Meanwhile, there should be a determined effort toward the invention of *some safe* efficient method of gas testing, so that the treacherous misnamed flame safety lamp may be entirely excluded from mines.

## Lake Coal Runs Eventful Course from Mining Field to Northwest Ports

Every Year About Twenty-five Million Tons of It  
Make Summer a Busy Season on the Great Lakes for the  
World's Most Massive Material Handling Machines

**L**AKE coal may travel as far as 600 miles by rail (1) and may go through the hands of as many as 10 train and yard crews before it gets anywhere near water. Finally it arrives in a yard on the lake front (2) at one of the dumping ports on Lake Erie. From here it is pushed by a switch engine up over a hump or "high grade," each car coasting down over a pit between rails. Out of this pit rises "the pig," a squat, heavy, pusher car hauled by a steel rope. The pig moves the load up a short grade and onto the car dumper.

A car of coal, in the grip of the dumping machine (3), is hoisted about 50 ft. in the air. Then, whoosh! The whole 50 tons goes down an apron and through a flexible spout into the vessel (4); cars are dumped one a minute. An operator in a cabin mounted on the apron manipulates the steam-operated spout, swinging

it to and fro like an elephant's trunk. Thus the load is trimmed in the boat so neatly that scarcely a shovelful is spilled over the top of each hatch. The coal then travels up the lakes 800 miles or so to a Lake Superior dock, in a boat that may carry 14,000 tons, or about six 50-car trainloads.

At the Head of the Lakes the boat ties up beside a dock that may be big enough to hold a million tons of coal and the unloading is done by gigantic Hulett (5) which gulp up 15 tons of coal at a bite, delivering each "bite" into a larry car that rides within the frame of the machine. This larry car transports the coal back from the dock edge and delivers it on the ground within easy reach of immense traveling bridge cranes, some of them 700 ft. long, which store the coal on any part of the great dock, ready for reshipment inland throughout the Northwest.

# Block System of Mining Coal Has Many Advantages

It Reduces Danger, Increases Percentage of Extraction and Results in Coarser, Cleaner Output—Room-and-Pillar Mines Can Be Converted to Block Method Mainly by Widening Centers

BY H. R. BISSELL

Chief Engineer Rosedale Coal Co., Morgantown, W. Va.

**C**ONTRARY to popular belief there is nothing complicated about the block system of mining coal. If the present room-and-pillar system is taken as a foundation and the centers of the rooms as well as those of the crosscuts are widened out to a maximum and uniform figure, the block system will result. Thus the relationship between the two methods is close.

It is surprising to find the number of operators who are still working upon the old idea of narrow centers. The mine maps of such coal producers would show that nine out of ten of them have large areas developed and standing in a semi-squeezed condition. The coal in such cases is mostly lost, or, if mined, is recovered only at an excessive cost. The fundamental idea of mining according to this method appears to be to concentrate in developing entries and rooms, spacing the latter as close together as possible so as to secure production more quickly, also to make the room breakthroughs easier to drive.

In such mines, from 50 to 60 per cent of the coal is secured in first mining. The balance is left as a necessary evil to be removed by pick and shovel at a higher labor expense, a lower production per man, a higher haulage cost, an excessive use of timber and a high cost for cleaning up falls and retimbering. The final output is a shattered dirty product which is a natural consequence of these adverse conditions. A large percentage of the coal also is entirely lost.

The block system of operation simply reduces to a minimum the coal removed in first mining. Large substantial blocks are left for pillar operations so that instead of pillar drawing being undesirable both as to cost and working conditions, the size of the blocks, and the protection they afford together with the concentration of labor rendered possible, make the work even more attractive than development from every standpoint. After a block system has been once established the major portion of the production from the mines is derived from the removal of the pillars. Development work easily takes care of itself and only 25 to 30 per cent of the coal is produced in this operation. Drawing of pillars is, of course, done by undercutting with two or more men working on each pillar.

## ALL PASSAGES ARE DRIVEN ENTRY WIDTH

In the accompanying illustrations, Fig. 1 shows a block system differing from many old room-and-pillar projections in the width of the centers only. This plan shows all work driven entry width, blocks 84 ft. each way with 24 per cent of the solid coal removed in first mining. This plan is particularly adaptable to the Pittsburgh bed, although under other conditions the rooms can be widened out providing the centers are likewise extended so as to give blocks of maximum size. The plan shows all rooms driven to their limit as soon as they have been necked. It will be found, however, that after getting a long break line estab-

lished, room development can be retarded by skipping two or three rooms occasionally and driving them only when required for the break line.

In Alabama I have seen mines employing 800 men of whom 12 were employed in drawing pillars that were badly squeezed. I have seen mines in that state 45 years old still working by the original methods under which they were started, that is taking 50 per cent of the coal in first mining and working out quarter-mile squares before starting pillar drawing. This results in the mines spreading over enormous

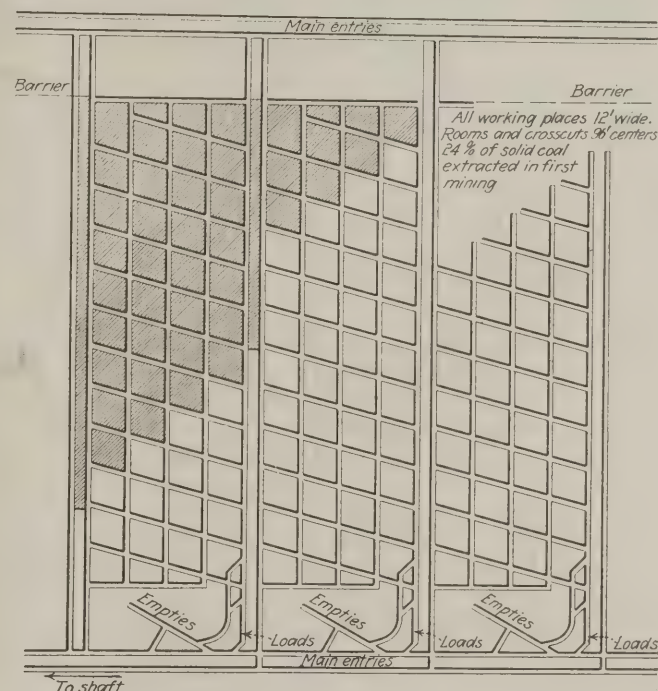

Fig. 1—A Mine Developed on the Block System

This plan differs from the ordinary room-and-pillar mine only in the width of rooms and the distance between centers. All passages are here driven entry width and the resulting blocks are 84 ft. each way. Only 24 per cent of the coal is removed in first mining, leaving the other 76 per cent for pillaring operations.

areas, four to five miles from the opening, while at the same time a large percentage of the coal is lost.

The principal objection to the block system in that region is that it is new and unfamiliar not only to the loaders, mostly negroes, but to the foremen as well.

Again in West Virginia mines may be seen that have been worked out to the extent of 70 to 75 per cent and then abandoned because it had become dangerous to draw the pillars. Such properties are sometimes purchased by a neighboring operation, in order to secure the villages that have been built on them, as well as to get the equipment installed.

An advance pillaring block system is shown in Fig. 2. This is well adapted to a comparatively flat bed and mechanical haulage because all pillar coal must be hauled parallel to the direction in which the butt entries

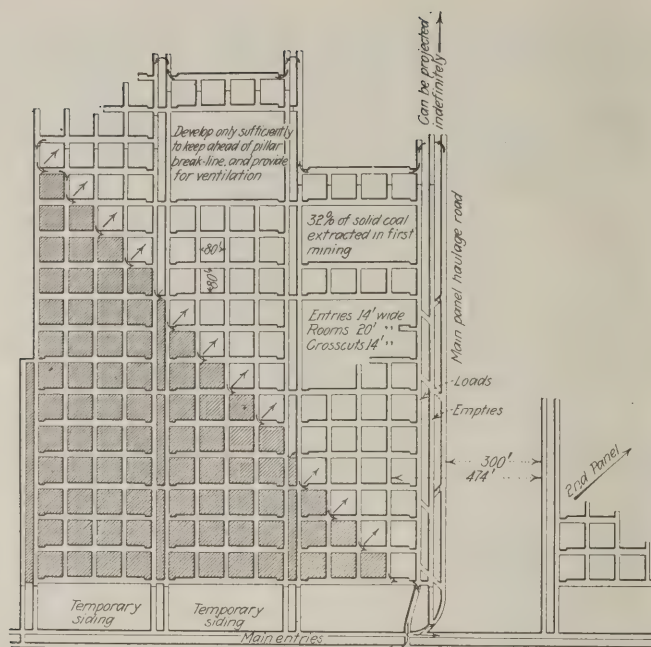

Fig. 2—Block System Particularly Adapted to Mechanical Haulage

This plan is especially adapted to comparatively flat beds. Rooms are driven 20 ft. wide on 100-ft. centers, giving blocks 80 ft. each way. First mining yields 32 per cent coal recovery. All pillar coal is hauled in a direction parallel to the butt entries.

are driven. This plan shows 20-ft. rooms and 80-ft. blocks with 32 per cent of the coal removed in first mining. However, for use in the Pittsburgh bed, entry width for all passages would be preferable.

In this plan efforts have been made to establish a break line as shown, after which development becomes secondary, the principal production from each panel being secured by concentrating on the removal of the line of pillars. Material such as track, etc., is continually moved forward as the break line advances and new sidetracks are constructed along the main panel haulage road. The barrier along this roadway not only provides protection while advancing but will furnish working places when the panel is finished and the chain pillar is ready to retreat. Some companies are projecting these panels a distance of 5,000 ft. or more.

A few of the many methods employed in removing blocks is shown in Fig. 3. The size of the blocks them-

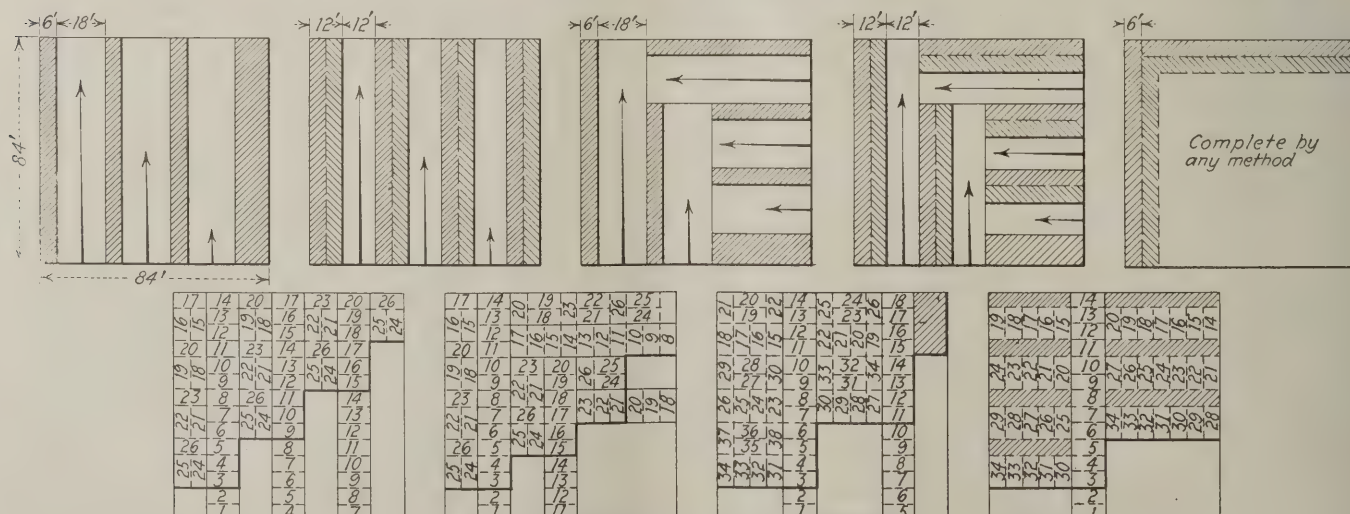

Fig. 3—One Method of Drawing Block Pillars

These pillars because of their size render the mine secure from squeeze, and any ordinary method of extraction can be followed with safety. Undercutters may be employed in pillar drawing to advantage.

selves makes the pillar operations secure from squeezes, safe for any reasonable method of pillar extraction and the work desirable for undercutting. These considerations form the chief arguments favoring this system.

For purposes of comparison with the block system, Fig. 4 shows the survey of a typical West Virginia "snowbird" opened during the war with a two-mile truck haulage to a private railroad siding. This mine produced 100 tons daily. The pillars will remain where they are shown.

Many of the largest companies in both West Virginia and Pennsylvania long ago changed to a block system. In Pennsylvania many mines have projections showing 100-ft. blocks, these being permitted by the mining law. The major portion of the tonnage, however, comes from smaller operations which have not altered their methods to any appreciable extent, and are hoping for

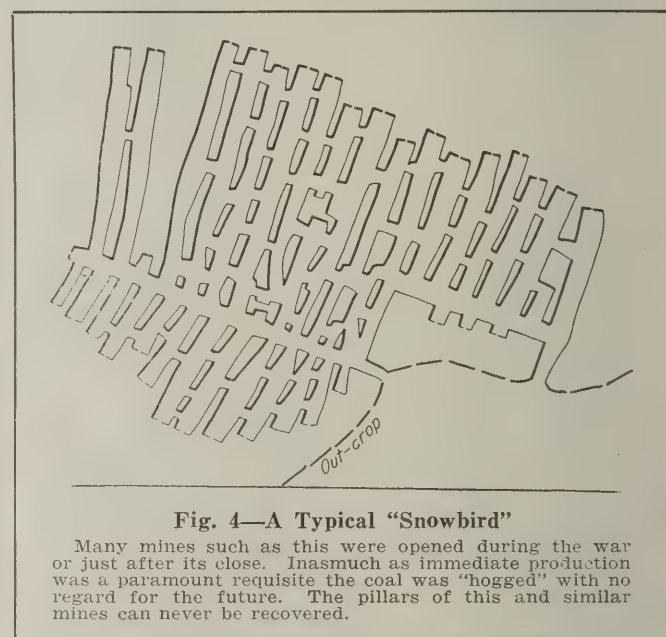

Fig. 4—A Typical "Snowbird"

Many mines such as this were opened during the war or just after its close. Inasmuch as immediate production was a paramount requisite the coal was "hogged" with no regard for the future. The pillars of this and similar mines can never be recovered.

another increase in prices which would allow them to withdraw standing pillars. When such a time arrives, however, the management may be so engrossed in retaining its labor and increasing its production that developments will be pushed still further and the next season will find the same old area of dangerous pillars.

# British Experiment with Bituloid as Dust Layer

Limited Trials Indicate Possibilities of Allaying Mine Dust with Colloidal Oil—Cannon Shots Into a Coal-Dust Cloud Fail to Ignite Dust Thus Treated—Further Experiments Appear Warranted

COAL DUST has long been recognized as a potent factor in mine explosions and one which contributes largely to their violence. Much effort has therefore been directed toward preventing coal dust from propagating an explosion. In general two means have been adopted to this end namely, (1) neutralizing combustible coal dust by mixing with it an incombustible stone dust and (2) wetting down accumulations of fine coal particles with various liquids the most common of which is water.

Unfortunately, probably because of the high surface tension of water and the somewhat greasy nature of coal, especially when in a finely divided state, water will not readily permeate a mass of coal dust. Furthermore water will in time dry out of dust leaving it free to be raised in the air almost if not quite as readily as if it had never been treated or wet down. In order to overcome this difficulty various

other substances have been added to or mixed with water to decrease its surface tension and increase its dust-penetrating ability. Soap, water glass, carbolic acid and various other substances have been tried for this purpose. All in varying degree reduce the surface tension and permit a more rapid infiltration of water into dust accumulations. Many of these substances also, upon drying, leave the coal dust so caked that it cannot be thrown into a cloud upon the initiation of a gas explosion.

Anyone who has observed the effectiveness of oil in laying the dust of a country road can readily appreciate that when applied to the coal dust of a mine it acts in a manner quite different from either water or stone dust. Strangely enough certain oils penetrate coal dust more readily than does gasoline and do not dry out for a long time. Such an oil possesses the highly desirable quality of seeping through the dust to the surface where it tends to catch and hold any other fine particles that may be floating in the air. Thus air in traversing a mine passage that has been treated with, say, a bituloid solution is purified rather than contaminated as it would be in traversing a passage that has been rock dusted.

Prof. Henry Briggs and Norman H. Wales recently presented a paper on the subject of "Colloidal Oil (Bituloid) as a Medium for Laying Coal Dust," before the South Wales Institute of Engineers. Some of the "high lights" of this paper are as follows:

The dominant factors governing the ability of a

liquid to wet down coal dust are the size of the dust particles, the surface tension of the liquid and some relationship not yet determined existing between the constituents of the liquid and of the dust. Of these the most important is surface tension.

Prof. W. M. Thornton in 1911 advocated the use of a liquid that served as a cement-like binder, but it is now believed that greater effectiveness can be attained

by employing a liquid that does not cake or cement the dust together but which dries with difficulty keeping the surface of the dust in a sticky or "tacky" condition. Bituloid, which is a heavy road oil intended originally for use on the surface, possesses the quality of remaining plastic for a long time. It readily seeps through dust deposits and keeps the surface moist thus quickly catching and holding any additional dust that may come in contact with it.

Bituloid is a milk-like substances consisting of:

Mexican bitumen, 15 to 20 per cent; green tar oil, 30 to 35 per cent; oleic acid and caustic soda, 1 to 2 per cent and water, 48 to 49 per cent. The ingredients of this mixture are so minutely divided and thoroughly mixed that they form a true emulsion the particles of oil and bitumen remaining in permanent suspension. In treating roads on the surface it is customary to add 19 parts of water to each part of bituloid, the resulting mixture thus containing about 2½ per cent of oil and bitumen. A stronger solution appears desirable for use on coal dust, and in most of the experiments performed with this substance a 10 per cent solution of oil and bitumen was employed.

Experiments thus far conducted with this material would seem to indicate that in application a coarse spray is preferable to a fine one. Furthermore the liquid should, if possible, be projected against the mine surfaces with appreciable force if best results are to be expected. If the mine passages are already well covered with coal dust two or three applications of bituloid in rapid succession may be necessary in order to bring the surfaces of the passage to the proper condition. Cleaning the surfaces and removing the dust present will facilitate the bituloid treatment and make more than two applications unnecessary as an initial treatment.

Once adequately treated most mine passages can be kept in proper condition by comparatively infrequent applications. The interval between treatments will, of course, depend on the rate of dust deposition and the drying power of the air current traveling. It is

estimated that one application in six weeks will be ample in most cases. The expense of laying dust by this means, of course is confined to the outlay for the material itself and the labor entailed in its application. The investment in equipment is small and there is no fixed charge for a preparation plant as with rock dust.

Several tests have been made with this material at various places. At the Eskmeals experiment station the floor of the experimental gallery, which is 200 ft. long and 7½ ft. in diameter was thickly strewn with coal dust. One half this length was then treated with a bituloid solution containing 5 per cent of oil and bitumen. The ends of the gallery were then boarded up and allowed to stand for three weeks. At the expiration of this time the boarding was removed, and it was found that the liquid had thoroughly wetted the dust, the surface still displaying an appreciable degree of adhesiveness. Dust readily was raised by the feet of the observers when traversing the portion of the tube where the material was untreated, but none was raised where the dust was bituloided.

#### EFFECT OF SPRAYING LASTED THREE WEEKS

At the Annesley colliery in Nottingham, England, two lengths of steel-timbered heading, 308 and 105 ft. long respectively and located near the downcast shaft bottom were treated on Oct. 6, 1922, with a bituloid solution containing 5 per cent of oil and bitumen. The volume of air traversing the heading where these applications were made was 32,544 cu.ft. per minute, the average saturation of this air being 74 per cent.

The longer section received a second dressing on Oct. 28. An inspection was made on Nov. 3, and it was found that the floor dust was damp and could be squeezed into a cake in the hand. The dust on the sides of the heading formed a plastic layer that required a knife for its removal. Under these conditions the effect of double spraying lasted three weeks after which freshly deposited dust was no longer retained, and another application of bituloid was necessary. In untimbered roadways carrying a high velocity of comparatively dry air the results obtained were not as satisfactory, the effects of an application disappearing in a few days, rendering retreatment necessary.

Tests of this method of laying dust were also conducted about the same time at the Bestwood colliery, in Nottinghamshire, England. These likewise indicated that a close connection existed between the drying power of the air current and the length of time that might logically elapse between applications of bituloid. In one haulage road 11 ft. wide and 6 ft. high carrying 33,000 to 35,000 cu.ft. of air per minute at 73 deg. F. and 90 per cent saturation, surfaces covered with stone dust that had been previously applied, when sprayed with 2 gal. of 5 per cent mixture per linear yard of heading, remained in good condition for a month, the floor being the first surface to show need for retreatment. During this time about 800 tons of coal was transported through this passage daily.

Early in December, 1922, a trial of bituloid was made in the Llanbradach colliery. This test was conducted on an intake haulage road. The velocity of air in this passage was 300 ft. per minute, the temperature 53½ deg. F. and the humidity about 80 per cent. The section selected was 240 ft. long. A part

of this distance was arched, part timbered and the remainder supported by "horse-shoe girders" backed by wood lagging. A large quantity of dust had collected on the roof and sides. That on the floor was kept wetted down by means of water sprays installed at intervals.

Without cleaning this passage and while the floor was wet an application of 20 per cent bituloid was made with a pressure pump. Under the circumstances no great success was anticipated. On examination fifteen days later, however, the treatment appeared to have been effective on the roof and sides but not on the floor.

Tests at the Newbattle Colliery, Midlothian, Scotland, conducted during November and December, 1922, gave the following results: (1) Bituloid caught and bound coal dust into a mass of such a character that it could hardly be expected that it would be thrown into a cloud in the air by any explosion wave however forceful. (2) It reduced the quantity of dust floating in the air. (3) A 10-per cent mixture of bituloid appeared to be most suitable. (4) A single application on dusty surfaces appeared to be of little value; at least two preliminary dressings were needed to afford the desired adhesiveness. (5) An effective cleaning should precede bituloid application. (6) Surfaces to which dust most readily adheres such as wood, are those to which bituloid also most readily adheres. (7) On the intake haulage road, where the tests were conducted, the surfaces retained their stickiness for over a month.

One objection advanced to the use of any material such as soap or bituloid for laying dust in mines is that such material unquestionably adds to the combustible content of the dust. As a matter of fact, however, a mixture of bituloid and coal dust no matter how thoroughly it may be dried out never attains such a condition that the dust could be raised in a cloud. It is believed therefore that an explosion of the mixture is thus rendered impossible.

#### BITULOID PREVENTS COAL-DUST IGNITION

In order to ascertain definitely by trial whether an application of bituloid solution would prevent the ignition of coal dust a series of experiments were made in a short narrow drift of the Straiton limestone mine, of the Shotts Iron Co., in Midlothian, Scotland. Obviously such tests could not be prosecuted in an operating coal mine. It was of course necessary to make such arrangements that ordinary untreated coal dust could be exploded without fail before trials were begun on treated dust.

Impressions made upon the eye were not reliable indications of the intensity of the explosion produced. The force of the blast of air created was more trustworthy, but the impression made on a photographic plate was more satisfactory still. A camera accordingly was used in recording results.

In order to ignite the dust a cannon with a 1½-in. bore loaded with 1 lb. of 2 oz. pellets of black powder and stemmed with 2 oz. of coal dust was fired electrically into the cloud of dust created by a "cloud raiser" placed in front of it and fired about one second previously. This cloud raiser was a lump of clay with a small vertical hole in its top and loaded with a 2-oz. pellet of black powder stemmed with 2 oz. of coal dust. The cloud raiser was placed 3 ft. in front of the cannon. With this arrangement 7 to 8 lb. of coal dust

distributed on shelving along the sides of the drift could be ignited time after time.

In order to simulate as nearly as possible the condition of maximum risk, the dust raiser and cannon were not fired until after bituloided surfaces of the drift had been sprinkled with a greater quantity of coal dust per unit area than would normally be deposited upon them between treatments and a certain time interval had been allowed to elapse. As no means could be found for distributing the dust evenly and uniformly hour after hour, it was all distributed at one application. At least a full day (24 hr.) was then allowed to pass before the cannon was fired.

The results of this procedure were as follows: On the first day the drift was cleaned and the surfaces strewn with 8 lb. of coal dust after which 6 gal. of a 10-per cent bituloid solution was applied. On the third and seventh days the dust was again sprayed with a bituloid solution of the same quality after which an additional 4 lb. of coal dust (making a total of 12 lb.) was distributed. This treatment was intended to simulate that administered to a dusty road where three applications of bituloid would be employed.

On the eighth day the surfaces were examined and it was found that the bituloid solution had absorbed the dust, with the exception of a little here and there. The surfaces were "tacky." The cloud raiser and cannon were then fired in the usual manner, but the photographic plate showed that no dust ignition took place.

On the sixteenth day the surfaces were again examined and found to be still adhesive. More coal dust, 4 lb. of it, making 16 lb. in all, was distributed. On the seventeenth day it was found that the bituloid had absorbed the additional dust. The cloud raiser and cannon were again fired, but the photographic plate once more showed no dust ignition. Four more pounds of coal dust then were distributed, making a total of 20 lb.

Again on the twentieth day the surfaces were examined and found to be adhesive. Once more the cannon was fired, but the photographic plate showed no dust ignition.

This series of experiments was terminated by a collapse of the wall along the side of the drift. This wall was eventually rebuilt, and the drift again rendered accessible. The surfaces that remained undisturbed were inspected on the seventy-eighth and ninety-eighth days after the first application of bituloid. Sluggish ventilation and high humidity were favorable to the slow drying of the bituloid. The dust remained closely bound in a soft matrix even fourteen weeks after the first treatment.

#### FURTHER EXPERIMENTATION APPEARS WARRANTED

These experiments, of course, were not conclusive, nor were they intended to be. Thorough demonstration can only be made by a long series of tests under widely varying circumstances. The results thus far obtained, however, would appear to warrant the initiation of such experiments.

This general method of allaying mine dust, although nothing positive concerning it may yet be said, would appear to possess certain more or less definite advantages and disadvantages. These might be briefly enumerated as follows: Rockdusting is the most efficient method of preventing dust explosions that has

yet been thoroughly demonstrated. This practice, however, particularly on roads that are seldom cleaned tends toward a pollution of the mine air rather than toward its purification. Working or walking in places encumbered with dry dust of any kind is unpleasant and may expose the men to dust diseases. Bituloid, repeatedly applied to dusty mine passages that are not systematically cleaned, in time will render such places almost impassable. Though a bulk sample from the floor, ribs, roof and timbers of a place that has been rockdusted may show 50 per cent of incombustible matter, inasmuch as the coal dust is deposited on top of the stone dust, the outermost layer or that first affected by an explosive wave will undoubtedly contain a higher percentage of combustible material. Bituloid impairs mine illumination instead of improving it. On the other hand its use would check, if it did not entirely prevent, the growth of fungi on mine timbers.

#### BITULOID OPENS WIDE FIELD OF POSSIBILITIES

Three other questions involved in the use of bituloid can only be determined from experiment or from experience. These include the effect, if any, of a current of air of high drying power; the effect of bituloid on the weathering of shaly rock, and the effect of spraying this material on the insulating cover of power cables. At the Annesley colliery some samples of shale were dipped in water and others were dipped in bituloid solution, after which they were all allowed to dry. Those dipped in water crumbled in a short time, but the others did not disintegrate.

As bituloid or some similar oil product appears to open a wide field of possibilities it would seem that some careful experiments as to the effects of its application would be fully justified. It is only through careful test that the possibilities and limitations of any process or material may be determined with accuracy.

This Big Chunk "Just Happened"

They didn't try to mine this 2 ft. 6 in. x 2 ft. 9 in. x 4 ft. chunk weighing approximately 2,200 lb. It just happened. The Pittsburgh coal bed (this piece came from the Pittsburgh Coal Co. Montour No. 9 mine, on the Montour R.R.) is noted for its well defined cleavage faces and butts at right angles thereto. This lump came down in a room face just as it is shown in the picture and this particular chunk has within itself no cleavages at all, although the surrounding coal is characterized by the usual rectangular faces. The man on the right in the picture is James Davidson, superintendent of Montour No. 9.

*Thew Shovel in Hanna Mine*

## They Are Solving Coal-Loader Problems at Hanna

Wyoming Thick-Seam Conditions Seem Ideal for Loading Machines Yet Heavy Time Losses Cannot Be Avoided—Small Units Save Money Even at 104 Tons a Day—Single Track with Switch Proves Best for Rooms

EVERY mine offers its own peculiar obstacles to mechanical underground loading. And in every one, when these problems are worked out, machine loading pays. In the No. 4 mine of the Union Pacific Coal Co., for instance, where coal is 32 ft. thick, where roof conditions are good and there is no forest of timber to contend with, T. H. Butler, mine superintendent, once thought conditions were ideal for loading machines. Loading machines are having their opportunity—Joys and big Thews working in conjunction—yet the “ideal” conditions managed to yield a large crop of adverse circumstances which Mr. Butler described in a recent discussion before the Rocky Mountain Coal Mining Institute.

But in spite of the adversities the machines “earned their keep” during the first six months of this year, as Eugene McAuliffe, president of the company, revealed. He said the Thews loaded coal for 52.4c. per ton, a saving of nearly 28c. a ton over hand loading, and the Joys saved 11c. a ton. Together the saving averaged 25.2c. a ton; but it was Mr. McAuliffe’s opinion that neither type of machine could have done it alone. The Joys made it possible for the Thews to do their work so well.

The system at Hanna is for the Joy machines to take out the lower 8 ft. of the 32-ft. seam, in rooms 32 ft. wide and sometimes 800 to 1,000 ft. long. The Thews then load out the next 18 ft. above, the aim being to leave 6 ft. of top coal to hold the soft sandstone roof. This scheme looks admirable on paper, but the seam pitches from 14 to 17 deg., which introduces complica-

tions, for it takes a long time and a lot of effort to move the Thews from room to room. The rooms are driven on the strike and planes are used on the pitch. When faults are encountered, the planes are driven between the faults.

The Joys averaged during that six months only 104 tons a day per machine and the Thews but 140 because they could not be kept running steadily. Mr. Butler said the machines undoubtedly would load the coal if it were possible to keep them in coal all the time, but there are always many seemingly unnecessary delays to be overcome. Changing cars, breaking lumps, pulling coal loose from the face that a machine will not dig, repairing machines and the heavy time losses due to moving the machine on the heavy pitch have been the main difficulties.

In January, 1916, the company installed a Type 1 Thew shovel, equipped with a 1½-yd. dipper, and in July, 1917, it installed a Type 0 Thew, equipped with a 1-yd. dipper. In 1918 two additional Type 0 Thew shovels equipped with 1-yd. dippers were added, making a total of four Thew shovels for this mine.

“The introduction of these shovels,” said Mr. Butler, “caused the employees much concern, and, like all departures from the old methods of mining, met with the indifference of some and the open antagonism of others, so that for some time the results obtained were not satisfactory.

“However, in consequence of constant supervision and changes in the method of haulage the results obtained at present, though not entirely satisfactory,

The Loading System at Hanna No. 4 Mine of Union Pacific Coal Co.

In order to make room for shooting down a great pile of coal in front of Thew shovels, the bottom 8 ft. is taken out by Joes in rooms 32 ft. wide and of various lengths up to 1,000 ft., depending on local conditions. The next 18 ft. is loaded by the Thews and 6 ft. at the top is left to hold the roof.

are much better, and the production and costs are reasonably good. The Thew shovels in use are mounted on traction wheels with swivel axle and move in all directions by their own power. Though the weight of each is approximately 20 tons, they are not as cumbersome as one would think and they are easily operated.

"The method used in working these Thew shovels is to shoot the coal down ahead of them and maintain two tracks, two cars being used on each track, so that a shovel is loading on one track while the driver is changing cars on the other. When the place is finished the shovel is run back to the first crosscut by its own power, and lowered to the next room with block and tackle, the roof coal in the crosscut being shot down to a height of 16 ft. to allow the boom to pass.

"With better results from the Thew shovels the officials of the company soon realized that it was necessary to find some means by which rooms would be developed faster than mere human power could drive them, for otherwise the Thew shovels would soon exhaust the working places available. So in November, 1923, the company purchased two Type 4BU Joy loaders. These machines met with the same indiffer-

ence and antagonism from the employees as had the Thew shovels. For a time the results were discouraging, but for the past six months they have been better, and at present, though production and costs are not entirely satisfactory, they are, in my opinion," says Mr. Butler, "reasonably good.

"As I see it, the big problem of successful mechanical loading is transportation, and that means working out a system of haulage so that empty cars are at all times available at the loader, or, better still, the development of a system of sectional conveyors to take the coal from the loader at the face to cars or to a conveyor on the plane.

"The blasting of the coal also is a matter of importance in the successful operation of mechanical loading, for the coal must be loose and of a suitable size to be readily handled. In this respect we are somewhat handicapped, as the coal is of a woody nature, with no cleavage or fractures, and has no roof parting to shoot to in the advancing places, all of which makes it difficult to provide coal so loose and of such size as to be handled readily by the loaders.

"How to lay the tracks in the advancing places so as to keep the cars as close to the loaders as possible also is a problem. It seems to us that the fewer tracks

**Joy Loader in the Hanna Mine**

The Joy machine is used to load out the big 8-ft. undercut in the mammoth 32-ft. seam, thus preparing the way for the surface-type Thew shovel which loads out 18 ft. of the rest of the coal. The Hanna bed dips 14 to 17 deg. and the delivery of cars is thus greatly hampered, but the shovel nevertheless makes a saving.

used the better. Our experiences have taught us that by keeping a 5-car parting 25 or 30 ft. from the face

and by using a single track from parting to face we get better results than by using two tracks, the loader crew pushing the loaded car from the machine to the parting and the empty car from the parting to the loader.

"For each Thew shovel we have a crew of three men, one operator and two trimmers, one of the trimmers shifting the cars from the shovel to the plane parting. For each Joy loader we have a crew of four men, one operator, two trimmers, and one driver. I notice in the mining journals that many operations have a crew of two men on Joy loaders, but owing to large lumps that have to be broken and the half loosened coal that has to be pulled off the face, our production from loaders would decline if we reduced the size of the crew.

"Our production from the four Thew shovels and the two Joy loaders in use will average 50 per cent of the output of the mine. The attached tabulated statements show the results being obtained by the use of mechanical loaders."

## Alberta Coal Field Soon to Be Opened

**P**ART B of the Summary Report of the Geological Survey of Canada, for 1923, just issued, contains an account of a preliminary investigation of the coal deposits along the Smokey, Hay, and Berland rivers, in northwestern Alberta, by J. MacVicar. Though this investigation is admittedly of only a preliminary nature, it gives a large amount of useful information about a region that, when opened by railway facilities, is likely to prove one of the most important coal areas in Canada. The investigation takes into consideration a strip of land 80 miles in length and 8 to 10 miles in width at the southeastern end and 25 miles wide at the northwestern end, extending in a northwesterly direction from Brulé, 180 miles east of Edmonton. In this area the thickness of the coal measures average 3,000 ft., and the individual beds range from a few inches up to 56 ft. thick. The coal varies in grade from bituminous to semi-anthracite, the lowest beds, because of the greater pressure to which they have been subjected, contain the higher carbon content.

These coal measures belong to the Kootenay formation, and where worked are noted for their evenness. Basing his calculations on this regularity and on the dimensions of the beds where they outcrop and at points at which they have been opened, Mr. MacVicar estimates that the area under consideration contains 10,000,000,000 tons of workable coal. The northwestern part of the area, which contains some of the thickest beds and is estimated to contain 7,000,000,000 tons of bituminous and 70,000,000 tons of semi-anthracite coal, has been withdrawn from location and is retained by the government as a national coal reserve.

At Brulé, in the southeastern part of the area, a considerable amount of development has been done and coal is mined for use on the Canadian National Ry. At this point the measures are 3,680 ft. thick and contain one 14-ft. and five 7-ft. beds. The top 700 ft. and the bottom 1,200 ft. of the measures contain no workable coal bed. Development in other parts of the area has been small, because there is no railway communication. The Canadian National has surveyed a route for a line to the north branch of the Hay River, which, with feeders, would give access to the first 40 miles northwest of Brulé. This road and also the Canadian Pacific

are considering branches into this district, which has been demonstrated to be one of the best agricultural regions in the Dominion. There is every reason to expect therefore that a railway will be built into this district in the near future.

## Salt Water to Avoid Fatigue

BY SIR JOSIAH COURT

**D**R. J. S. HALDANE has suggested that the cramps of mine workers in hot mines may be due to excessive loss of sodium chloride through profuse and prolonged sweating aided by the drinking of much water. In consequence experiments were made with a few miners who were given a weak solution of water when at their work. The proportion of salt was about  $\frac{1}{4}$  per cent or 10 g. in 1 gal. of water. The result was satisfactory and justified its use.

It occurred to me to try the use of salt at a colliery where the air temperature at the coal face was considered high. I interviewed six miners as they left the Warsop Main pit. The four places in which they had been engaged had temperatures varying from 79 to 81 deg. F. All the men consented to take my advice and put salt in the drinking water that they brought to the mine. After a month's trial they all said they were less tired than usual after their work was over. One man not only said he was less fatigued but less anxious for his usual nap after his return home. The wives declared their husbands were more energetic when they came off shift. Another man said that attacks of cramp in his leg had ceased to trouble him since using salted water.

The boilermen at Warsop Main were working in an average air temperature of 96 deg. F. (dry). On my recommendation they added half a teaspoonful of salt to every quart of water they drank. They usually consumed four pints daily. Twelve days later I saw them again, and every man was pleased with the experiment. They all stated that when they reached home in the evening they felt less tired than they had been when drinking unsalted water.

From a paper read before the Institution of Mining Engineers, London, Oct. 2, 1924. (Eleventh Report to Committee on "The Control of Atmospheric Conditions in Deep and Hot Mines".)

## News Of the Industry

### Coal Stock Report Again Emphasizes Need of Distribution Data

Features Surprising to Trade Reveal Lack of Statistics Comparable with Those on Production—Demand for Figures Becoming Insistent—Interesting Light Cast on Industrial Conditions

By PAUL WOOTON  
Washington Correspondent of *Coal Age*

Correspondence reaching Washington shows that there was general surprise in the coal trade and among consumers that the country's stocks should have been 47,000,000 tons on Sept. 1, as shown by the report issued jointly by the U. S. Geological Survey and the Bureau of the Census. In some quarters there is a disposition to doubt the returns. Those who hesitate to accept the figures in the stock report base their attitude on the fact that production was low during April, May and June—lower than in those months of 1921—yet the stock report shows a reduction of only 15,000,000 tons since Jan. 1 and 4,000,000 tons since June 1.

The explanation of the apparent contradiction between the production and stock figures is that consumption of coal has been at a low ebb. In fact, it had fallen to a lower point than had been realized.

The stock report presents conclusive evidence that the country has been going through a period of dull business which almost could be characterized as a depression. In the iron and steel industry, for instance, which affects coal more than do many light industries, the depression was severe. The output of pig iron in July was the lowest in any month since February, 1922. To be specific, production of pig iron in July was 1,785,000 tons. This was barely half the rate of production in July, 1923, when it was 3,678,000 tons. Even the July, 1922, production was 2,403,000 tons.

#### Leaders Mum on Eve of Election

Naturally on the eve of an election business leaders are not saying much about the depressed state of industry, but the figures in the stock report tell an interesting story.

In the first quarter of the year the output of iron and steel was well up around the level of 1923, a very prosperous year, but beginning in April it began to tumble "like Niagara," to use an expression often employed by Dr. Garfield. In so far as the iron and steel industry is concerned it certainly sank to depression levels in midsummer. It is now moving upward at an encouraging rate, but has not recovered to the point where its consumption of coal is heavy.

One of the reasons why the present period of sluggishness in business has passed without much comment is that business has been spotty. Building and certain other activities have been brisk, but the heavy industries that are the large consumers of coal have been in the doldrums. They have been conspicuously absent from the coal market.

It is noticeable that the changes in coal stocks since Jan. 1 reflect closely the trend of general business. From Jan. 1 to June 1 the liquidation of stocks went on rapidly, but from June 1 to Sept. 1 it was very slow. The stock report shows clearly that the severe depression in coal was not due merely to undigested stocks held by consumers, but was due mainly to the fact that the country was passing through a period of depression. The coal market would have been dull even if there had been no stocks. The fact that there is a heavy reserve still to liquidate is discouraging to the producers of coal and some are counseling curtailment of production, which has been rising sharply for six weeks. There can be no doubt that this would be good business, from the standpoint of the coal operator, but from the consumer's point of view it is regarded apparently as good business to continue to buy coal at present prices so as to maintain the reserve.

#### Coal Reserves Comfortably Large

The stock report shows that the country's reserve of coal is comfortably large. There is no prospect of a shortage this winter unless something unforeseen should occur. It would not be in the public interest for consumers to be lulled into a false sense of security and allow their stocks to fall below the danger line. There is increasing evidence, however, that American consumers at last have learned that ample reserves above ground constitute their best insurance against high prices.

Consumers of anthracite, however, are not displaying the same wisdom. Anthracite stocks for the most part still are in the hands of the retail dealers. The sudden advent of severe weather would wipe out these stocks quickly. Retail storage is designed for the gradual movement of a considerable portion of the coal handled. Stocks

### These Miners Know How To Cut Mine Costs

Twelve union miners who have been making \$12 to \$15 a day each by running the Crawford Coal Co. mine near Brazil, Ind., on a co-operative plan have been ordered by the district union organization to quit or be ejected from the union for 99 years. The union officials declared the men, by doubling up on jobs and otherwise reducing operating costs, were producing coal so cheaply that other operators could not compete with them.

now on hand are not sufficient to supply more than immediate needs. A run on this reserve might come over a wide area and make it impossible for the producers to supply all the coal needed on such short notice.

The appearance of the stock report, carrying with it a great surprise for the entire trade, emphasizes anew the need for distribution statistics that are comparable, at least, with those covering production. That the demand for such figures is becoming more and more insistent is indicated by the great amount of attention given the problem as applied to all commodities, at the meeting of the Eastern Division of the Chamber of Commerce of the United States in Washington.

### Coal Traffic at Cincinnati Breaks Record

As a coal-handling city Cincinnati is rapidly approaching the records established by Pittsburgh, if continued increases in interchange figures as regards coal loadings may be accepted as an indication.

Following the announcement several weeks ago that the highest previous interchange record had been passed, J. A. Morris, district manager of the American Railway Association, in his weekly letter to the Car Service Division at Washington last week reported a new high mark of 13,500 carloads of coal handled during the preceding seven days in the local terminals. This was an increase of 802 cars compared with the previous week. An increase also was reported in coal bound for lake ports.

Of the 17,336 empties interchanged during the week, 12,377 were open tops going to the mines. All coal loading roads except the L. & N. have been able to supply 100 per cent car equipment for the entire week.

## Coal Exporters Charged With Unfair Competition

The Federal Trade Commission charges unfair methods of competition in the marketing of coal to South America in a complaint issued against the Gano Moore Co., New York City, and the Gano Moore Coal Mining Co., Philadelphia, Pa. M. Rea Gano is named individually as a respondent in the citation, and as the president and active director of the two responsible companies.

The complaint alleges that the respondents in their conduct of their business in export trade have accepted orders and received payment from foreign customers for coal of a specified quality and quantity, to be delivered in several shipments at specified times, and wilfully or through negligence have caused to be delivered for the coal so ordered coal of a quality inferior thereto, and have failed to make deliveries in the quantities and at the times specified. On the contrary, the complaint states, deliveries of inferior coal have been made and in less quantities and at later dates than specified, the total amount being much less than the total quantity ordered, thereby engaging in unfair competition with competitors in the United States engaged in foreign commerce who bid on and furnish goods of the desired quantity and quality, and ship at the specified time. The respondents, the citation continues, bring into disrepute and injuriously affect the entire exporting trade of the United States, and unfairly injure all competitors who fulfill their agreements and undertakings.

### Tried to Raise Price

According to the complaint, respondents represented that they were unable to make deliveries under existing contracts although at the same time repeated offers were made to the same purchasers to ship larger quantities of coal of the same kind and quality but at greatly increased prices, also offering to ship under the original contract provided the purchaser agreed to pay an increased price and to enter into contract for additional shipments of coal at increased prices.

Further allegation of the complaint is that the respondents in order to defeat the purposes of alleged export regulations of the United States, which restricted the export of coal to a certain percentage of the contract quantity, proposed to the Central Argentine Railway, Ltd., that they enter into a fictitious contract for 200,000 tons of coal, the railway at the same time to receive a letter from respondents to the effect that the contract was in effect for but 50,000 tons. The railway refused to accept this proposal.

The methods employed by the respondents in the conduct of their business in export trade, according to the citation, have injured and damaged generally the reputation and the business of persons of the United States lawfully competing with respondents in export trade, and have brought such competitors into disrepute with purchasers in South America.

## Now the Athletic Mule

"I've been reading those 'bright mule' stories," says a mining man. "Let me tell you about an athletic mule I knew out in a thin-seam Iowa mine. I took control of a mine out there and was viewing it for the first time. I had noticed the mules all were about 14 hands high. In looking around underground I came to a place where a boulder in the roof stuck down right over the track, leaving a clearance of only 3 ft. 10 in. Not being able to figure out how a 14-hand mule could get through a place like that, I sat down to see. Pretty soon there came a little trip on the run. I'll be darned if that tall mule didn't just juke down and slip under that boulder like a dog goes under a fence, and away they went without a pause. I had to laugh. Show me any other animal 14 hands high that can do any such stunt! That's my 'bright mule' story."

What's yours?

## Fewer Mine Accidents Under His Régime, Says Pinchot

In an address at Erie, Pa., on Oct. 23, Governor Pinchot attributed the reduced number of mine fatalities and accidents in Pennsylvania during the past year to the economies and efficiency of his administration. The politically useful state employee has been dropped, he said, and jobs have been awarded to the efficient.

"The results speak for themselves," he said. "In the past, for example, many thousands of miners in Pennsylvania have lost their lives in cave-ins, explosions and the hundred and one sources of danger in the underground shafts."

"We have undertaken to reduce these accidents by eliminating the sources of danger. Better inspection all along the line has resulted in the saving of the lives of many of the miners. The statistics prepared by the Mines Department at Harrisburg conclusively prove that this department has rendered a service to the families of the miners that cannot be calculated in mere dollars and cents."

"There has been a steady and gratifying decrease in the number of fatal mine accidents. In proportion to hours worked, the year 1923 showed a considerable improvement over 1922, but 1924 has far outstripped any other year of the last decade in the decreased number of mine deaths. Thus in the first eight months of 1923, 388 men lost their lives in anthracite mine accidents. During the same period of 1924, 333 men were killed in the anthracite mines, or a reduction of 55 lives. Similarly, 293 men were killed in the bituminous mine accidents in the first eight months of 1923, while but 228 died in the soft coal mines in the same period in 1924. That represents a saving of 65 lives in the bituminous mines. Better inspection certainly aided materially in reducing by 120 the number of mine fatalities in a single year."

## September Soft-Coal Exports Second Highest of Year

Total exports of bituminous coal from the United States during September amounted to 1,502,829 gross tons, the second heaviest monthly shipments during the current year and an increase of almost 110,000 tons over August exports, according to a report by the Coal Division of the Department of Commerce. Exports to Canada, totaling 1,201,280 tons, increased by more than 150,000 tons over August exports and were exceeded only by July shipment to that destination.

Overseas shipments of bituminous coal during September, amounting to only 281,886 tons, compared with 335,671 tons in August, were the lowest of the year; in fact September is the only month in which overseas exports have fallen under 310,000 tons. The chief cause of the decline in these shipments is the fact that exports to Italy dropped from 89,040 tons in August to 33,590 in September. There were only two other European countries to which American bituminous coal was shipped in September, 27,067 tons going to France against 37,401 tons in August, while 1,100 tons went to Spain.

Important increases occurred in shipments to parts of Central America and the West Indies. Among these were exports of 10,278 tons to Barbados, 6,755 to Trinidad and Tobago, and 7,674 tons to the Virgin Islands, to which destinations no coal was shipped during August. Exports to Cuba, however, fell from 67,183 tons in August to 46,184 tons in September, and to the French West Indies shipments during September amounted to only 1,118 tons against 9,452 in the previous month.

Although shipments to Brazil during September amounted to 77,282 tons against 80,892 in August, total exports to South America increased, amounting to 94,223 tons against 90,389 in the preceding month. This increase was due to shipments of 15,660 tons to Argentina in September whereas there were no shipments during August. An unusual feature of the coal export trade was the shipment of 1,776 tons to Japan in September.

Exports of anthracite during September, when shipments were the second highest of 1924, were 327,322 tons against 257,090 tons in the preceding month, the increase being due to heavier exports to Canada, 321,282 tons going to that destination in September against 246,316 in August. Exports of coke from the United States during September totaled 41,804 tons against 42,308 in August.

The Illinois Coal Traffic Bureau, in a complaint filed with the Interstate Commerce Commission Oct. 27, attacks the rates on bituminous coal from southern Illinois and the Belleville groups of mines as being unduly preferential to western Kentucky, to the extent that the existing differentials are less than 50c. per ton over the southern Illinois rates and 85c. per ton over the rates from the Belleville group, on coal moving via the East St. Louis gateway.

## U. S. Anthracite Operators Visit European Mines

Much first-hand information about the methods pursued in mining under various conditions in England, Wales, Scotland, Belgium and Germany was gained during a trip of 55 days recently completed by S. D. Dimmick, vice-president and general manager of the Glen Alden Coal Co., and H. M. Warren, consulting electrical engineer of the same company, both of Scranton, Pa.

The visit of the Scranton mine officials to England was made at the invitation of Harry Walker, chief inspector of mines of Great Britain, who addressed a meeting of the Engineers' Club of Northeastern Pennsylvania in Scranton last May. Mr. Walker greeted his American friends upon arrival in England and prepared an itinerary for visits to the mines of England, Scotland, and Wales under his jurisdiction. The visitors found much to interest them, especially in the anthracite region of Wales.

### Welsh Mines Lined with Brick

Mr. Dimmick was impressed with the depth of the mines in Wales. He said the average shaft is from 1,600 to 2,000 ft. deep as compared with average depths of 600 to 1,400 ft. in the anthracite field of Pennsylvania. He also noted the use of bricks to line the shafts in contrast to the American practice of using timbers, and steel ropes as conductors for the cage in place of wooden guides. The absence of surface subsidences, which cause so much trouble to anthracite operators in Pennsylvania, also impressed the visitors. The depth of the veins from the surface practically obviate such disturbances. Many of the mines recover all of the timber, the visitors learned, by mining out all of the coal and dropping the roof.

In Brussels the Scranton operators visited mines at Liege and Charleroi. While in the Ruhr district the party made its headquarters at Cologne. Here they were able to inspect the Frederick Hinrichs mine, regarded by the Germans as the most modern of its kind in

Thomas Fraser

Assistant professor of mining engineering in the University of West Virginia, in succession to C. E. Lawall who has been designated acting head of the department. Mr. Fraser is a graduate of the mining department of the University of Illinois, where he studied under the late Prof. H. H. Stoek, E. A. Holbrook and A. C. Callen. He also was employed for four years on investigative work with the U. S. Bureau of Mines, principally in coal preparation and subsidence problems.

the world. Mines in Essen, Oberhausen and Duisburg, located in the occupied territory along the Rhine River, also were visited by Mr. Dimmick and Mr. Warren.

Several operators of German mines in Essen and Duisburg informed Mr. Dimmick that during the month of March, 1925, they contemplate coming to this country to spend several months on an inspection tour in the bituminous and anthracite regions. It is expected that they will come to Scranton, where they will be the guests of Mr. Dimmick. The director of the Gutehoffnungsuile mine, in the Ruhr, is already in this country on an educational trip. He is expected in the hard-coal region soon.

## Commercial Coal Stocks Up. Say Purchasing Agents

Commercial consumers of anthracite and bituminous coal on Oct. 1 had in their bins 52,468,725 net tons, according to the monthly survey of the National Association of Purchasing Agents. This is a decrease of nearly 11,000,000 tons when compared with May 1, but an increase of 1,143,725 tons when compared with the tonnage on hand on Sept. 1 of this year. The survey shows that the estimated production in September was 48,418,000 tons and the consumption 34,217,000 tons, as compared with 33,637,000 tons in August.

In its survey the association says that business increased a little in September over the previous month if coal consumption is a fair criterion by which to judge. It is significant, however, that the majority of large corporations used about the same tonnage in September as in August while the smaller ones showed an increase. The consumption of coal for heating industrial buildings during September amounted to 528,342 net tons, or 1.5 per cent of the total production.

## Assigned-Car Order Postponed Again

The effective date of the assigned-car order of the Interstate Commerce Commission, restricting and regulating the distribution to coal mines of privately owned cars and cars for railroad fuel, which was to have been Nov. 1, was postponed by the commission on Oct. 23 until Dec. 15.

The commission's decision in the case, made on June 30, 1923, held to be unjust the practice of railroads in assigning private cars and system cars for railway fuel to bituminous coal mines in excess of the ratable share distributed to bituminous coal mines upon their lines which do not receive assigned cars. After the issuance of the first order postponements have succeeded each other with monotonous regularity.

(a) Includes Alaska, California, Georgia, Idaho, North Carolina, Oregon and South Dakota.

## Delay of Assigned-Car Order Arouses Producers

The action of the Interstate Commerce Commission in delaying until Dec. 15 the effective date of its order abolishing the use of assigned cars in the procurement of railroad fuel is being criticized widely. There is a general desire in the coal trade to have the uncertainty removed. In some quarters the commission is accused of lacking the courage to put its order into effect in the face of the violent opposition which it aroused among the carriers. It will be recalled that the carriers were so certain that the commission would not abolish assigned cars that they made only a perfunctory effort in opposition to the proposal when the matter was first brought before the commission.

The dilatory tactics of the commission have so aroused some of the producing interests that inquiry has been made as to possible legal steps to require the body to express itself. While there is no statutory way of requiring the commission to take action, it is thought that just as effective results can be obtained by a Senate resolution inquiring into the causes of recurring postponements.

A probable explanation of the delay is thought to be that the commission is closely divided on the questions involved in the matter of assigned cars and mine ratings. The postponements, some think, are being ordered in the hope that some of the differences may be smoothed out.

The coal consumption of various industries as shown by the returns of the 1923 census of manufactures, now being issued, include the following: Rubber products, 544,105 tons; manufacture of steam and electric railroad cars, 44,630 tons; stoves, 94,783 tons; pianos, 102,108 tons; haircloth, 3,291 tons; manufacture of gas machines, gas and water meters, 24,120 tons; watches, 38,929 tons; grindstones and pulp stones, 10,884.

## Six Hard-Coal Firms To Be Consolidated in \$20,000,000 Company

*Special to Coal Age*

Scranton, Pa., Oct. 27.—A twenty million dollar merger of coal properties in Luzerne and Lackawanna counties will be consummated here within the next few days, according to information from Frank W. Childs, of New York, who is back of the biggest consolidation plan yet attempted in the anthracite region. A syndicate of bankers of New York City are understood to be part of the combine seeking control of the collieries. The following companies, according to Mr. Childs, are included in the merger: Kingston Coal Co., Grand Tunnel Coal Co., at West Nanticoke; Jermyn Coal Co., Old Forge; Midland City Coal Co., of this city, and the West Ridge Coal Co., of this city with the Carbondale Coal Mining Company of Carbondale.

The Kingston company and Jermyn company properties are the largest listed in the combine. The former company with coal titles will sell for \$6,000,000, according to the option, it is said, and the latter company will be bought for \$8,000,000 if the option is taken up. The Grand Tunnel Coal Co. is another large corporation in the lower section of the hard-coal field. The Midcity and West Ridge collieries are known in mining circles here as excellent properties. Figures on the estimated coal acreage involved in the transaction were not made available, as detailed information regarding the collieries is not being given out for publication.

It is understood that Mr. Childs has handled virtually all of the details and obtained a majority of options held by the syndicate. For some months back experts have looked over the properties included in the list, together with a number of companies not in the combination. Most of the options expire this week and a definite announcement of whether or not the merger will be put through will be made before the end of the week. Originally, it is said, the

## Coal Mining Institute Balloting On

Official mail ballots have been sent out for the election of officers for 1925 of the Coal Mining Institute of America. The candidates are as follows: President, A. C. Callen, Urbana, Ill., and Nicholas Evans, Johnstown, Pa.; vice-presidents (three to be elected), J. M. Armstrong, Pittsburgh, Pa.; A. C. Fieldner, Pittsburgh, Pa.; J. B. Hanford, Morgantown, W. Va.; W. C. Hood, Uniontown, Pa.; Eugene McAuliffe, Omaha, Neb., and J. J. Rutledge, Baltimore, Md.; secretary-treasurer, T. P. McTigue, Pittsburgh, Pa., and H. D. Mason, Jr., Ebensburg, Pa.; managing directors (ten to be elected), Ralph Beerbower, Pittsburgh, Pa.; Denis Boyle, Johnstown, Pa.; D. R. Blower, California, Pa.; F. W. Cunningham, Somerset, Pa.; M. D. Cooper, Pittsburgh, Pa.; Charles Enzian, Windber, Pa.; J. H. Evans, Mather, Pa.; W. G. Fear, Indianola, Pa.; W. E. Fohl, Pittsburgh, Pa.; William Hart, Parkers Landing, Pa.; A. E. Holbrook, State College, Pa.; A. B. Kelley, Greensburg, Pa.; R. M. Lambie, Charleston, W. Va.; Lee Long, Dante, Va.; Richard Maize, Uniontown, Pa.; J. W. Paul, Pittsburgh, Pa.; William Rigg, Pittsburgh, Pa.; Edward Stridle, Pittsburgh, Pa.; S. A. Scott, MacDonald, W. Va., and Fred Vinton, Indiana, Pa.

deal contemplated the merger of some fourteen companies in Lackawanna and Luzerne counties, but a recent turn of events has reduced the number to six. As first contemplated, the consolidation included the von Storch, Legitts Creek, the Spencer and Nayaug companies. Mr. Childs said that the name of the proposed company would be the Consolidated Mining Co. The company will have its main offices in this city.

Plans for financing the deal have been worked out, according to those who have been in close touch with the progress of negotiations. The latest merger, if it is completed, will make the fourth and most important in the anthracite field in the space of a few months.

## Output and Value of Coal from Indiana Mines in 1923

## Commerce Department Indispensable Force in American Business

Under Hoover's Direction It Has Become Powerful Factor in Promoting Self-Government in Industry—Helped Bring About Three-Year Miners' Wage Agreement

From an agency with a reputation of being engaged largely in statistical and other stereotyped tasks the Department of Commerce within the last three years gradually has taken on vitality and momentum until now it is roaring along like a great motor and has become a vivid, powerful and indispensable force in American business.

Unquestionably Mr. Hoover's greatest accomplishment as the Secretary of Commerce, and the one which promises greatest return to the public, is his promotion of constructive self-government in industry. He has shown conclusively how these voluntary forces can bring American industry to a new high plane of efficiency. Codes of ethics have been established in many lines of business. Many others are in the making. Practices that are unfair to the public and to others in the same line of endeavor are being specifically listed and condemned. The way has been pointed out for industry and it is lifting its own standards and taking steps to see that they are maintained.

Despite all the ultra-conservatism that characterize the captains of industry Secretary Hoover broke through the crust of their reticence and has them co-operating with the government and with each other in an effort to put our economic life on a higher plane and to instill in all a new appreciation of the rights of others.

In the matter of trade promotion, leadership also is vested in those engaged in the businesses concerned. No step is taken until it is established that the trade wants it and needs it. That this policy is bearing fruit is shown strikingly by the fact that new business secured during the last fiscal year, as a result of suggestion or help from the Bureau of Foreign and Domestic Commerce, totaled \$529,000,000.

### Additional Funds Needed

If American business continues to increase its use of the Bureau at the rate maintained during the last three years, the point soon will be reached where more appropriations must be forthcoming. In fact, the handicap of inadequate financial support has made itself apparent in recent months.

Much more is done in the Bureau of Foreign and Domestic Commerce than trade promotion. There is a protective service which is of inestimable value.

One of the main reasons for the remarkable expansion in the use of this bureau unquestionably was the reorganization under which commodity divisions were set up. This form of organization is essential if leadership is to come from industry. The commodity divisions are under the immediate direction of specialists who have wide acquaintance in the industries with which they are familiar. They maintain the closest possible contact with

the individuals and with the associations in a particular industry, an advantage which is lost when organization is on a regional basis.

A notable series of studies is being made by this Bureau of those raw materials which are subject to arbitrary control abroad to the detriment of American consumers. The steps which can be taken to protect American consumers from unfair practices in other countries have been set forth in such a way as to promote production in other areas, to stimulate research and to encourage search for substitutes.

The new Division of Domestic Commerce is carrying into practice the ideas of business men in the effort to reduce the wastes and costs of distribution.

In the effort to insure lowest possible prices to the consumers and to increase the returns to the producers, the division of Simplified Practice, set up by Secretary Hoover, has been doing result-getting work in eliminating excess variety. It is taking many other steps to eliminate waste in industry.

### Defends Legitimate Trade Bodies

With a display of courage rather uncommon on the part of one holding political office, Secretary Hoover early in his term came to the defense of legitimate trade associations just at the time that these organizations most needed an outstanding champion.

Recognizing the far-reaching benefits of bringing ocean-going bottoms to the ports of the Great Lakes, thereby reducing the transportation charge against the products resulting from the labor of forty million people, Secretary Hoover proposed the creation of the St. Lawrence Commission. President Coolidge approved the recommendation and appointed Mr. Hoover as the commission's chairman. Under his auspices essential economic studies now are being made which will have an important bearing on the project, which, in addition to the waterway, involves the harnessing of 2,000,000 hp. of water power in an area where industrial development cannot expand much further until this power is made available.

Much has been done under Mr. Hoover's direction to call attention to the fact that electrical interconnection in the Northeast, the principal industrial section of the country, is not keeping pace with the best practice elsewhere. Studies have been made and maps prepared which emphasize again the need for interconnection, the construction of large steam central stations at strategic points, and the development of more water power. As a result of these studies the conclusion was reached that it would be possible to reduce coal consumption in the area by more than 50,000,000 tons annually,

power could be made available at lower rates, the factor of reliability could be improved, electrification of railroads could be made feasible, and power could be made available on farms so that much manual labor could be replaced by mechanical devices.

One of the great assets of the American business man is the statistical service furnished by the Bureau of the Census. Since the advent of Mr. Hoover there has been rapid expansion in the production of current figures which make available to all interested an accurate picture of the conditions under which operations are being conducted. Facts gathered by 116 trade associations, 55 government organizations and a large number of trade periodicals are compiled in highly serviceable form in the monthly publication *Survey of Current Business*. Nearly 1,500 business movements are portrayed through statistical tables, graphic charts and text material. It has popularized the use of index numbers. All industries are put on a comparable basis. General trends of production, stocks on hand and unfilled orders are available at a glance.

### Industrial Efficiency Increased

Under Mr. Hoover's direction the Bureau of Standards, the greatest physical laboratory in the world, has taken on new life. It has made a large number of technical studies which are of great value in making possible improved methods of production. Better utilization of raw materials has resulted from its researches.

Secretary Hoover played no inconspicuous part in bringing about the three-year wage agreement in the coal industry. He has consistently urged "peace and transportation" as the two most important steps which could be taken toward the stabilization of that industry. He made an effort just prior to the strike of 1921-1922 to effect an agreement providing for arbitration of the renewal of the wage agreement. The mine workers refused to agree to the proposal, but subsequent events revealed the lack of wisdom of such a course. After the strike was called Secretary Hoover effected a voluntary agreement whereby 85 per cent of the output was held down to the Garfield scale of prices. He has used the full weight of his influence to induce public utilities and other large consumers of coal to put in large stocks during the seasonal lull in coal production.

One of Mr. Hoover's first major accomplishments came early in his term and grew out of the conference on unemployment. He was able to enlist organizations of employers and employees, state officials, municipal officials and a large number of public-spirited individuals. A large program of public works was launched and other steps taken which gave employment to two million persons.

Out of this conference grew the study of business cycles. The report issued in the course of this study carried conclusive evidence that periods of depression are the natural outcome of a period of speculation and waste. It is believed that this report has made a sufficiently wide impression to arouse general interest in curbing inflation and booms.

## Big Sandy Coal Association Combats Discrimination

A coal tax at so much per bushel, like the present gasoline tax of 2c. per gallon, is being advocated in Kentucky. The Northeast Kentucky Coal Association met at the Ventura Hotel, Ashland, Ky., Oct. 23, to discuss the situation and to attend to other business. The coal men desire that the tax be placed on tobacco instead of on coal, seeing that the money has to be raised and that competition in coal is so severe that the tax would reduce output.

Instead of trying to make coal pay for good schools and good roads the coal association is in favor of the \$75,000,000 bond issue which has been proposed. The coal men present voted to indorse the issue. The Associated Insurance Companies are asking for an increase in rates, though they were raised a year ago. The operators' association has filed a demurrer, attacking the right of the State Compensation Bureau to fix rates, contending that they have only powers of approval.

The association will compile exact facts on taxes and insurance premiums paid and on the compensation paid to employees. This will be used in combatting unfavorable legislation. Previously it has sent out inquiries and not more than 40 per cent of the companies addressed made reply. On this occasion the association will make a search of court-house records and thus will obtain information as to the taxes paid by coal companies.

The association has lost many members during the recent slump in prices, companies withdrawing to avoid payment of dues, which are now 7 mills per ton, yet in the last six months the association has obtained new freight rates saving operators 27c. per ton, opening new markets to the west for lump coal and affording the operators of the Big Sandy an opportunity to enter the tidewater market.

Delbert H. Pape, assistant to the executive secretary of the National Coal Association, said that the dues in most other local associations run from 1 to 3c. per ton with other special assessments. Harry L. Gandy, executive secretary of the National Coal Association, said that a barrel of cement costs roughly as much as a ton of coal, yet the members of the cement manufacturers' association pay dues of approximately 7c. per barrel.

Coal to the extent of 146,716 tons was used in connection with the manufacture of chocolate and cocoa products during 1923, the Bureau of the Census reports. Similar figures covering other industries are as follows: Steam and other packing, pipe and boiler covering, and gaskets, 145,596 tons; pulp goods, 131,421 tons; needles, pins, hooks and eyes, and snap fasteners, 24,216 tons; music, printing and publishing, 2,192 tons; excelsior, 5,163 tons; peanut grading, roasting, cleaning and shelling, 9,848 tons; linseed oil, cake and meal, 73,608 tons; toys and games, 32,041 tons; refrigerators, 70,894 tons; flavoring syrups and bitters, 95,177 tons; iron and steel forgings, 610,191 tons; pumps, 84,789 tons.

## Call Outlaw Strike of 10,000 Hard-Coal Miners Despite Order by Lewis

Special to Coal Age

Scranton, Pa., Oct. 25—For the second time in as many weeks a general grievance committee has overridden the expressed orders of John L. Lewis, international president of the United Mine Workers, and has called a general strike in the anthracite field.

The latest general walkout, ordered for yesterday morning by the general grievance committee of the Pennsylvania & Hillside Coal & Iron Co., took effect in the face of contrary orders by the district union officials and the international president. As a result 10,000 men are idle, and all collieries of the Pennsylvania & Hillside company in the Pittston district are closed.

District union officials are keeping silence in anticipation of advice from the international president. The situation to them is the same as that when the Glen Alden grievance committee called a strike.

The action of the Pittston union men in defying their leaders has precipitated one of the most serious situations in the history of the union in view of the specific orders of President Lewis that the men remain at work as provided in the wage agreement. Only yesterday President Cappellini transmitted recent orders from President Lewis to the executive committee of District No. 1, which were said to contain the admonition, that continued insubordination on the part of the grievance committees might result in suspension or expulsion of members from the union.

This threat, however, falls on deaf ears in the Pittsburgh region, where at least 90 per cent of the unauthorized or "outlaw" strikes go into effect. Several groups of alleged radicals, who are said to have been prominent in the election of Rinaldo Cappellini as president of the district, are going their ways without any particular fear of being excommunicated from the union. Cappellini has several times been placed in embarrassing positions as a result of the actions of his supporters in the Pittston section. On one occasion the union local in which he holds a card called a strike without consulting the district officers. The local was on strike for several weeks and its grievance with several others, which the men charge are not being given attention, has resulted in the present outlaw strike.

In dismissing for want of jurisdiction the appeal of W. L. Stickel from decisions of lower courts adverse to him in his suit against the Big Laurel Coal Co. for title to coal lands in West Virginia, the U. S. Supreme Court on Oct. 13 declined to question the authority of the West Virginia Legislature to enact laws by which the state assumes title to lands on which taxes have not been paid for a period of years. No written opinion was handed down, the court acting upon authorities cited by attorneys for the coal company. Stickel claimed title because of inheritance from an old land grant. The coal company acquired the lands after they had been taken by the state because of not being entered on the tax books.

## Three Miners Die in Blast In West Kentucky

Three miners were killed by an explosion the night of Oct. 22 in the Hart Coal Corporation's mine near Madisonville, Ky. Fourteen others were in the mine at the time but came out almost unscathed. The cause of the blast had not been finally determined when this was written but unofficially it was believed to be due to a windy shot fired by Paul Wheeler, 22, one of the three victims. He had been married but four days. The other two men who died were Thomas Chinn, assistant mine electrician, and Gilland Joyce, machinist. Brent Hart, president of the company, estimated the property loss at about \$20,000 and said the mine would be partly closed down for about sixty days for repairs.

## N. C. A. Cost Accounting and Tax Committee Named

S. Pemberton Hutchinson, president of the National Coal Association, has appointed a special tax and cost accounting committee, with especial reference to a recent decision of the Solicitor of the Bureau of Internal Revenue on the subject of allowable expense deductions and replacements in coal-mine operations after normal output has been reached, as authorized at the recent meeting of the Board of Directors of the association. Following is the personnel: M. L. Gould (chairman), president, Linton Coal Co., Indianapolis, Ind.; J. D. Francis, vice-president, Island Creek Coal Co., Huntington, W. Va.; Michael Gallagher, general manager, M. A. Hanna Co., Cleveland, Ohio; C. F. Richardson, president, West Kentucky Coal Co., Sturgis, Ky.; Geo. B. Harrington, president, Chicago, Wilmington & Franklin Coal Co., Chicago, Ill.; W. D. Ord, president, Empire Coal & Coke Co., Landgraff, W. Va.; Frank S. Love, president, Union Collieries Co., Pittsburgh, Pa.

The committee has been called to meet at Washington, on Nov. 12, at which time the subject will be thoroughly discussed and the attitude of and the action to be taken by the National Coal Association determined. The change of interpretation of the Internal Revenue law as to what constitutes allowable deductions, according to an opinion by the Solicitor of Internal Revenue, presents a serious situation to the great majority of the bituminous coal producing companies, especially on account of unadjudicated returns in prior years. The committee includes men of broad experience in the industry who have intimate personal knowledge of the line of demarcation that should be drawn between ordinary industries and what may be termed to be a "westing industry," such as the mining of bituminous coal.

President Hutchinson had intended a committee of eight members, but inasmuch as one acceptance of the appointment has not yet been received, the announcement of the eighth member will be deferred for the time being. Prior to the committee meeting another prominent operator will be added.

## Practical Pointers For Electrical And Mechanical Men

### Cutting Down Old Brushes for New Use Is True Motor Maintenance Economy

**R**EDUCING maintenance costs is one effective method of promoting economy in any industry. This article is to describe a method which has effected worth-while savings in motor maintenance merely by making use of old brushes that are too often thrown away.

Any industry that employs a great number of direct-current motors and other direct-current apparatus, finds at the end of a year that the expenditure for carbon brushes alone amounts to a considerable sum. It is generally known among electrical maintenance men that when one-half, or more frequently one-third of a carbon brush is worn away, it is seldom dependable for further service in the type and size of holder for which it was originally intended. As a result the worn brush is scrapped and a new one put in its place.

It seems never to have been a common practice in electrical repair shops to refit the worn brushes of large sizes to the brush holders of motors employing brushes of smaller dimensions. This is probably due to the fact that the alteration of the brush destroys the copper coating that originally was placed on it in order to effect a maximum contact with its mounting, and that considerable time frequently may be required to fit the brush to the holder in which it is to be used.

However, this operation of refitting old brushes to new mountings of smaller dimensions may be shortened and made more accurate by sawing, grinding or filing the brushes to approximately the right size and then by forcing them, with an arbor-press or other suitable apparatus, through a gage as shown in the accompanying illustration.

This gage may be made of cold-rolled steel with openings shaped to the various dimensions of the smaller brushes that are to be made. Care must be taken to leave the edges of the openings accurate and sharp and they should be case-hardened to insure a maximum life to the edges, which trim the brush. One strip of steel long enough to accommodate gages of several sizes may be employed, and the various sizes should be stamped at the openings prior to the hardening of the

steel. Such a gage can be stored more conveniently and found more easily when needed than would several gages each made of a separate piece of steel.

One feature worth special mention, is that a carbon brush may be a carbon brush but all grades of carbon brushes are not adapted to any one service any more than one grade of brush is applicable to all services. Therefore, when resizing brushes, care should be taken that the various grades of the larger brushes are made only into the smaller sizes required by motors employing the same or a similar grade of carbon. If this practice is not carefully followed, considerable trouble may be experienced with the commutation of motors equipped with brushes of an unsuitable grade.

After the brushes are sized, they should next be drilled or recessed for the attachment of shunts. Detachable shunts may be attached after the brush

Fig. 1—Sizing Gage Makes Work Easier and More Exact

After the brush has been cut nearly to size and filed it can be pressed through a gage and made to fit the brush holder so that it will not chatter.

is copper coated, while shunts that are not detachable should be secured to the brush prior to the coating. Permanent shunts may be attached by placing them in the vertical hole as shown in Fig. 2, and filling the horizontal hole with molten solder, taking care that sufficient heat is applied to the carbon as well as the solder.

After the shunt is attached the brush is coated to effect a metallic contact in the mountings. This process is of a more specific nature than those just described but it is often essential. Several methods are employed. However, I will mention only two which are in most common use.

One consists of impregnating the carbons with wax so as to prevent the blue vitriol solution from penetrating. The carbons are then brushed with quicklime and without further preparation are placed in a copper sulphate solution and the copper deposited electrolytically. This solution can be prepared in the proportion of 1 lb. sulphate of copper and 1 lb. of sulphuric acid to each gallon of water. First dissolve the sulphate of copper in the minimum amount of hot water that will

take it into solution and then add the remainder of the water cold. After this add the required amount of sulphuric acid. When the solution is cooled it is ready for use.

Another method that has become very popular is to bring the carbon

FIG. 2  
Drilled for the  
Shunt  
Pigtails should be carefully attached to the carbon. Two holes may be drilled, as shown, and one filled with solder which runs into the braid.

to almost red heat, then dip it into molten tin, afterward covering it with a layer of ammonium chloride. Then make the carbon a cathode in a copper cyanide bath and plate the carbon to about 0.2 of a mil, in thickness. After plating, the brushes must be washed, alternately dipping them in hot water and cold water and allowing them to remain in each bath from 5 to 10 minutes. Then the brushes must be carefully dried at about 110 deg. C. to remove all water from the pores.

ROYCE L. GRIMES,  
Electrical and Chemical Engineer  
Cleveland, Ohio.

### Using the Trolley Wire As a Meter Shunt

Split-type portable current transformers were developed to satisfy the urgent need for a means of measuring, with fair accuracy, the flow of current in an alternating-current line without the necessity of opening the circuit to insert the ammeter or its transformer. Many times it is likewise desirable to determine the amount of direct current flowing in a section of trolley wire or large feeder line. However, it is seldom done because of the cost and difficulty of inserting the meter or its shunt into the circuit.

This difficulty can be overcome by using the correct length of the conductor itself as a shunt. Fig. 1 shows the method of connection and Table I, which was copied from a mine electrical engineer's notebook, gives the necessary length of conductor between meter lead connections ( $a$  in Fig. 1) when using an ammeter or millivoltmeter which requires 100 millivolts at the terminals to bring the pointer to full scale reading.

This table was computed by using

Fig. 1—Measuring Direct Current Without Opening the Circuit

Using the conductor as a shunt will give readings which are sufficiently accurate for most mine feeder tests. One of the greatest chances of error lies in misjudging the sizes of stranded conductors.

the following formula which was derived from Ohm's law:

$$L = \frac{M}{A \times R}$$

Where L = distance in feet of conductor between the points where meter leads are attached.

M = millivolts required at meter terminals to give full-scale reading.

R = resistance in ohms per 1,000 ft. of trolley wire or other conductor.

As the formula makes plain, it is necessary to know the millivolt capac-

Fig. 2—Connecting Meter Leads

Connections to trolley wires are most conveniently made by using 20-amp. test clips. Special care should be exercised in getting a good connection to stranded conductors. Clean the surface, pull the clamp quite tight and have it touch as many as possible of the outside strands.

ity of the instrument used. This value is generally stated by a note on the meter scale or attached inside of the cover. The large majority of the portable ammeters for use with shunts are 100-millivolt capacity. If the millivolt value is not stated then the manufacturer should be asked to supply the information.

It will be recognized that this method of using the conductor as a shunt cannot be highly accurate. Errors are introduced by inaccurate placing of meter connections, temperature changes in the conductor and variations in the size

and length of meter leads. Such errors may amount to several per cent, but nevertheless the readings obtained will generally be sufficiently accurate to give the desired information.

A very satisfactory method of connecting to a grooved or figure 8 trolley wire is shown in *a* of Fig. 2. Here a 20-amp. test clip or battery charging clip, is used. This connection will not interfere with the passing of trolley wheels along the wires. Another easy way of making the connection is by means of ordinary trolley feeder clamps. A method of using a pipe grounding clamp for attaching the leads to a large stranded conductor is illustrated in *b* of Fig. 2.

## Can You Judge the Quality of An Adhesive Tape?

There are many grades of adhesive tape. A few are of a quality suitable for the purpose for which they are intended; many others are entirely unsuitable for any service. In the former class, quality must be the sole consideration, irrespective of manufacturing cost; in the latter class, quality is ignored in favor of low production cost.

The principal function of an adhesive tape in wire and cable splicing is to provide a firmly adhering, weather resisting, mechanical protection to a splice already properly insulated. The essential characteristics, therefore, of a high-grade adhesive tape for such a purpose are toughness and durability of fabric, the greatest possible adhesive strength and the longest weathering property.

The usual off-hand method of judging the adhesive qualities of a tape is to determine if it feels sticky." There is, however, a vast difference between "adhesiveness" and "stickiness." A tape which seems extremely sticky to the touch generally has little or no adhesive strength.

A much-used specification for determining the adhesive strength of a tape is:

"The adhesion between adjacent layers of the tape shall be such that when a strip of tape 2 ft. long is taken from a roll and wound upon a mandrel one inch in diameter, under a tension of 10 lb. per inch of width at a rate of 30 in. per minute and allowed to stand for 3 min. with the weight attached, a weight of 4 lb. per inch of width shall not cause the plies to separate at a rate greater than 30 in. per minute.

The test shall be made at a room temperature not less than 21.1 deg. C. or 70 deg. F. nor more than 23.9 deg. C. or 75 deg. F., the sample having been kept within these limits for at least 30 min. immediately preceding the time of testing.

"The mandrel shall be so free in its bearings that a weight of 1 oz. will cause it to revolve freely when sus-

pended from a cotton string wound in a single layer on the center of the mandrel."

The conditions of such a specification must be carried out scientifically and exactly, in order to obtain reliable data on adhesiveness. A variation of any one of the conditions will entirely alter the results. This essential property of a high grade tape—adhesiveness—cannot be determined by any casual or superficial means, such as sense of touch, etc., a careful test should be made to obtain accurate comparative results.

## The Starter "Hopeless," and No Spare Available

Where 220- or 440-volt three-phase motors are used to drive fans, hoists and the like, it is usual to place the transformer installation within 25 or 50 ft. of the motor. The most common arrangement is a bank of three single-phase transformers having series-multiple low-voltage windings connected to deliver the desired voltage. When such is the case it is a simple matter to fix up a temporary starting arrangement to serve as a substitute for a damaged starter.

A few feet of wire and a three-pole double-throw switch, or two three-pole, single-throw switches will do the trick. The three extra wires, as shown by the dotted lines in the accompanying illustration, are run from the transformers and connected to the clips on one side of the switch. The motor is

## Emergency Starting Method

A standard transformer connection except for the wires shown by the dotted lines. Throwing the switch to the left delivers half voltage to the motor for starting.

started on half voltage by throwing the switch to the left, then given full voltage by throwing it to the right, which is the running side.

When making such an emergency connection it is imperative that the starting and running leads be tied to the switch with the proper regard for the phase rotation, in other words so that the motors will tend to rotate in the same direction for either position of the switch. The plan used for obtaining half voltage is sometimes employed as a permanent method of supplying small, low-voltage, three-phase motors from conveniently located transformers which were installed primarily for other duty.

Table I—Conductor Length to Be Used as a Shunt

# Production And the Market

## Unseasonable Weather Causes Temporary Setback In Bituminous Coal Market

An unprecedented stretch of unseasonably warm weather has taken the edge off the demand for coal in many sections of the country, with the result that the market has been hard put to hold its own. This taken in conjunction with the grumblings of those who expected more of an improvement than there was any sound basis for has caused a temporary setback to even the conservative elements in the industry. Small-lot buying, only sufficient for current requirements, is again in evidence in many quarters, and as a natural consequence prices are none too firm. The fact is that though output, sales and prices have been climbing gradually, the gains have not been sufficiently heavy to enable the producers, except those in non-union fields that have been able to reduce wages to the 1917 level, to make a decent profit.

### Production Mounts in Eastern Ohio

Competition of the keenest character has to be brought to bear to get in on the business that is going. Then too the impending end of the lake shipping season looms as a menace that may release coal to compete in other fields. Nevertheless it is worthy of note that output in the eastern Ohio field has reached the highest level since early in February.

Coal Age Index of spot prices of bituminous coal halted for the time being in its upward climb, after seven consecutive weekly gains, standing on Oct. 27 at 176, the corresponding price for which is \$2.12—the same as on Oct. 20.

There was a marked increase in activity at Hampton Roads last week, dumpings of coal for all accounts during the seven-day period ended Oct. 23 totaling 384,268 net tons, compared with 326,124 tons handled during the previous week.

Coal movement up the lakes likewise mounted during the last week, dumpings at Lake Erie ports during the period ended Oct. 26, according to the Ore & Coal

Exchange, being as follows: For cargo, 819,869 net tons; for fuel, 39,998 tons. This compares with 735,770 and 40,787 tons respectively for the previous week.

After ten weeks of steady increase, bituminous coal output reacted during the week ended Oct. 18, when, according to the Geological Survey, 10,255,000 net tons was produced. This was a decline of 298,000 tons from the week ended Oct. 11, when the output was 10,553,000 tons, according to revised figures. The falling off was due partly to the observance of Columbus Day. Anthracite production, on the other hand, registered a slight

gain during the week ended Oct. 18, 1,750,000 net tons having been produced, an increase of 13,000 tons.

Conditions have eased somewhat in the anthracite market with demand a trifle slower, though the line companies are easily moving output and independents are disposing of tonnage with comparatively little difficulty. Stove coal is the least plentiful of domestic sizes, but the demand for nut has picked up markedly. Egg is comparatively easy. Barley is moving the easiest of the steam sizes, buckwheat and rice being slow for this time of the year. Independent prices are holding fairly firm at last week's levels. Save for a few operations that have not been able to resume since the flood a few weeks ago, most of the mines are nearing maximum production.

### Estimates of Production

(Net Tons)

#### BITUMINOUS

	1923	1924
Oct. 4.....	10,699,000	10,275,000
Oct. 11 (a).....	10,953,000	10,553,000
Oct. 18 (b).....	10,684,000	10,255,000
Daily average.....	1,782,000	1,709,000
Cal. yr. to date (c)...	443,359,000	363,156,000
Daily av. to date.....	1,799,000	1,469,000

#### ANTHRACITE

Oct. 4.....	1,949,000	1,425,000
Oct. 11.....	1,943,000	1,737,000
Oct. 18.....	1,978,000	1,750,000
Cal. yr. to date.....	75,492,000	72,763,000

#### COKE

Oct. 11.....	284,000	127,000
Oct. 18.....	286,000	146,000
Cal. yr. to date (c)...	15,332,000	7,871,000

(a) Revised since last report. (b) Subject to revision. (c) Minus one day's production to equalize number of days in the two years.

### Midwest Runs Slowly

Continued warm weather is doing its stuff in Illinois, Indiana and Kentucky. Demand has sunk to a point that makes nut and egg sizes extremely difficult to move, and even lump, which has been oversold in the better fields, is dragging slightly here and there with no immediate probability of a change in prices. Production is lower. However, circulars on lump are well maintained in such regions as southern Illinois, Indiana Fourth Vein and Mt. Olive, Ill. Central Illinois' attempt to increase from \$3 to \$3.25 a short while back failed so utterly that \$3 remains the absolute top for that field. Kentucky, both east and west, is having its difficulties finding a place to put most coarse sizes, so that the circulars of those fields on lump and egg in and around Chicago are pretty hard to hold.

Steam coal has firmed up for several reasons, but price levels have not risen. One or two of the big steam buyers in the Chicago district, whose storage piles have been sink holes catching large volumes of distress coal at absurdly low prices all summer and autumn, have made steam contracts for the winter, thus taking them out of the spot market. The slump in domestic production due to warm weather was another factor tending to stiffen up screenings. But to counteract these several other big steam buyers withdrew from the market entirely during the past week, thus reducing the demand. They are waiting for

colder weather and heavier production to pull steam prices down again. The general result of these counteracting forces is that steam quotations are maintained more closely than they have been for weeks.

Domestic business is easing around St. Louis. Cold weather stimulates it and the last week or two of warm weather has brought about a relaxation although prices have not changed. Coal dealers as a rule are pretty well loaded up, but there is a shortage of high grade lump. Mt. Olive lump is in fairly good demand, but Standard is slow with no call. Local wagonload steam shows considerable improvement although the tonnage is far under what it was a year ago on account of the inroads of electric power. Carload steam is hard to find. Country domestic has slipped a little while country steam demand is unusually light and is for small nut and not screenings.

### Kentucky Moves Some Coal

With the exception of a little Harlan fine gas block and some of the finer grate coals of the Straight Creek and Jellico fields, \$3.25 appears to be the top for best block coal in Kentucky, a few southeastern Kentucky mines getting as high as \$3.50 on some business, while a few operators are reported as quoting \$3.75. The eastern Kentucky block market is \$3@3.50; lump, \$2.50@3; egg, \$2.25@2.50; nut, \$1.75@2; mine run, \$1.50@1.75 and screenings are 10c. a ton weaker at 75c.@ \$1 a ton.

Coal Age Index of Spot Prices of Bituminous Coal F.O.B. Mines

	1924		1923	
	Oct. 27	Oct. 20	Oct. 13	Oct. 29
Index .....	176	176	174	184
Weighted average price .....	\$2.12	\$2.12	\$2.10	\$2.23

This diagram shows the relative, not the actual, prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the United States, weighted first with respect to the proportions each of slack, prepared and run-of-mine normally shipped, and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke; 1913-1918," published by the Geological Survey and the War Industries Board.

Movement has been good and mines are operating at capacity, but haven't much business booked ahead, and can't advance prices in the face of mild weather, without bumping into competition from union fields.

In western Kentucky block coal is quoted at \$3@\$3.25; lump and egg, \$2.75@\$3; nut, \$1.60@\$2; mine run, \$1.50@\$1.80; and screenings, 60@75c. Screenings are in big supply in all sections, and move only at low prices.

Chilly weather is resulting in slightly better orders from retailers and domestic consumers, and rural demand is improving a shade. Utility demand is increasing with shorter days, along with fairly active industrial consumption of power.

Good car supply and fair labor conditions are making for steady production. With the exception of the Central City district of western Kentucky, which is still partly strike bound, there are not many tippie mines inactive.

Northwest Trade Not Brisk

The market at Duluth is firm in both hard and soft coals and the price is as last quoted. However, trade has been unusually poor within the past week, due to the weather and the fact that dealers are pretty well stocked up. On top of their other troubles cancellations on orders are beginning to come to the docks from such utilities as the Minnesota Power & Light Co. Water power supplied by the recent rains has reduced coal demand.

Shipments to the docks continue reasonably heavy. Thirty cargoes were received last week, of which one was hard coal, and fourteen are on the way, but none of this is anthracite. It seems that the docks are starting to cut down on their shipments of anthracite. This is natural, as

200,000 tons more will more than fill any needs, and anthracite is not in demand anyway.

The feature of the Head-of-the-Lakes market is still Pocahontas. In fact two of the docks are not taking carlot orders for lump, although they are still supplying their retail trade. Mine run Pocahontas is coming into favor because it is \$2.75 less than lump at the dock, and those who use it in their furnaces say that it is just as good.

There is no change in conditions around Milwaukee, which awaits the onset of seasonable weather. A slight improvement in the flow of orders is reported; also a continuance of equipment trouble—difficulty in obtaining gondolas, which are preferred in most cases to the hopper carriers that are available. No change in prices is noteworthy. Receipts by lake in Milwaukee during October, up to the 22d, were 87,240 tons of anthracite and 277,684 tons of bituminous coal, making the total for the season 659,894 tons of anthracite and 1,917,994 tons of bituminous coal.

Western Business Is Spotted

More mild weather has made it easy for Southwestern operators to catch up completely with long fall orders. Retailers are now somewhat overstocked and running time in Kansas is shortening. This naturally reduces the supply of screenings, the demand for which continues fair. Oklahoma has settled most of her labor troubles with consequent higher production. This hurts Arkansas, which had already begun to suffer from warm weather and from the fact that cotton-gin trade is sold up for the fall. Arkansas semi-anthracite lump has dropped 25c. to \$5.50@\$6.75. Mine run is \$3@\$3.50 and screenings \$1@\$1.50 with considerable shading. Henryetta (Okla.) lump is \$5.50; nut, \$4; mine run, \$3.25 and screenings, \$1.50.

Colorado running time has been picking up with better markets. Last week mines averaged 31 hours and only 20 per cent of lost time was checked against "no market." Production is heavy enough from most fields now so that with the first real cold spell both operators and railroads will have their hands full. Routt County got its usual bad car service from the Moffat Road last week, attributing 61 per cent of lost time to car shortage. A slight increase in price has taken effect all along the line on domestic sizes from the southern Colorado fields.

The heavy movement of crops in the mountain states is beginning to cause a shortage of cars in the Utah coal fields. If the weather continues mild, operators say the situation will not grow serious; but if winter sets in early there may be a coal shortage. Prices, both retail and wholesale, are steadier than for months. The labor situation is excellent. Industrial demand for coal is normal for the season. Retailers have a 30-day supply of coal in the yards at Salt Lake City.

Ohio Markets Feel Stimulus of Cold Snap

The seesaw season is on at Cincinnati with the end of the lake season in sight. A couple of frigid days cut down suspension orders and refusals considerably, but coal on consignment in railway yards is not a healthy sign and the glutting of the Chicago markets with coal from the smokeless fields has made the local trade cautious. Still, there has been no distinct break in prices, and perhaps best of all is the strength of mine run. Slack is about the same as last week. Interest centers upon the probable prices of smokeless for November. Screenings are none too strong with the old quotation of \$1.10@\$1.25 prevailing. River business is still held up by the dry season in the upper valleys.

Colder weather has stimulated domestic trade at Columbus. Smokeless grades and splints are in the best demand and there is a fair trade in Hocking, Jackson and Pomeroy grades and also in Kentucky varieties. Retail prices are steady at recent levels. The car shortage on certain West Virginia lines is causing some concern but is not sufficient to add much strength to the market. Weakness in steam grades is the bad feature of the trade. The worst situation is in screenings, which are very plentiful owing to the larger production of lump and egg and consequently prices on that grade are extremely low.

Lethargy has overtaken the Cleveland market. The steam trade is particularly dull, due to industrial inactivity. During the week there have been many instances of nut and slack, usually 10c. a ton over slack, selling at the same price. These grades are not in such demand at this time

as to maintain the usual spread in the prices. Spot prices on other grades remain unchanged, with no tendency to reduction. Production in the eastern Ohio field during the week ended Oct. 18 was the largest of any week since early February. The domestic trade is not quite as active as it was several weeks ago.

There is more movement at Buffalo but it is not pronounced enough yet to affect price. There is some prospect of a car shortage before the crest of the grain movement has passed, but the railroad men say that there will be no serious shortage if there is any, so the situation is not likely to change much right away.

### Oversupply in Pittsburgh Market

There seems to have been too much loading of coal at Pittsburgh, but it does not appear that as yet there is any considerable accumulation of coal on track, and there are no reports of actual "distress" sales to avoid demurrage. There has been no definite price decline and this seems to be due to prices having been thoroughly shaken out six months ago. The district has been running at 50 per cent or more since the middle of September.

### New England Inactive but Hopeful

Bituminous trade in New England can hardly be described as active. There are inquiries in the market, and because coal men have been starved for so long they are inclined to regard a few crumbs as a feast. Prices are less depressed, and there are those who feel they will grow steadily firmer to the end of the year. Most of the buying is confined to Southern coals.

The present range of No. 1 coals at Hampton Roads is \$4.40@\$4.50 per gross ton, f.o.b. mines, with \$5.65@\$5.75 approximately the level at Boston on cars. Portland factors have been able in some cases to extract \$5.90 and even \$6 from small buyers, and at Providence sales have been continued on the \$5.50 basis.

All-rail shippers have as yet hardly begun to feel any firmer tendency. What little coal is sold by this route is still coming forward in dribbles and at prices that still rest on the hard pan of irreducible cost determined several months ago. Shipments via the Philadelphia and New York piers are still light, and there is no hope of any considerable improvement during November. The highest grades that compete at all with Pocahontas and New River are close to \$5 per gross ton, f.o.b. vessel at Philadelphia.

### Atlantic Markets Gain, but Slowly

Growing demand has not yet affected prices materially at New York. Business is a little slower, due in part to weather conditions. Line demand is more pronounced than buying at tidewater. Quality is playing a more prominent part in sales, prices being secondary if the prospective buyer can be assured of a suitable coal. Receipts at tidewater are averaging larger than for many weeks. Most of the coal is on contract.

A little more tonnage is being moved at Philadelphia, but as yet there have been only slight price changes. Prices seem a bit firmer at present low levels and with all indications that this is the low water mark. Stocking up seems to be general, but there has been a freer offering of gas slack the past week or so, caused, no doubt, by the increased domestic demand in the West for screened coal. The most favorable news is of a few charters for export coal.

The coal trade at Baltimore seems to be marking time till election. One of the hopeful signs is the steady increase

of inquiry on future deliveries for industrial use. So far, however, the easy supply from the mines, keeping well abreast of all demands, has prevented any increase in prices. In the face of a fall off in exports for the 24-day period of October as compared with the similar period of September, which included all activities of that month, there is a distinct feeling of encouragement in the line of foreign trading as a result of inquiries now developing from north coast Mediterranean and South American ports.

The Birmingham steam market is showing better form and there is increased activity in the domestic trade. Business being booked from industrial sources generally is assuming a healthier tone. Lumber and cotton mills and hydro-electric power companies are in the market to some extent on account of low water. Bunker business also is reported slightly better. While quotations on steam for the most part remain unchanged there is a tendency toward higher figures as basic market conditions improve. Domestic prices are firm in the face of stable current demand and the absence of adequate stocks in many sections.

### Anthracite Markets Are Easier

Easier conditions prevail in the anthracite market at New York. Independent coals are not moving rapidly although so far operators and sales agents have had no difficulty in disposing of output at last week's prices. The old line companies move their tonnages easily. Weather conditions have not been conducive to heavy consumption and householders, especially in the suburbs, have delayed putting in their winter coal. Stove coal is the shortest of the domestic sizes. Demand for it continues strong. Chestnut moves without any trouble, while egg is easy but not accumulating. Buckwheat and rice are in slow call for this time of the year. Barley is the easiest to move and the better grades are bringing full company price schedule.

A couple of heavy frosts at Philadelphia brought householders out eagerly after fuel and dealers are now urging for coal. None of the snap has gone out of stove coal, but the demand for nut now outstrips all other sizes. The mines are again near maximum production, though a few are still closed down entirely. Retail prices are a trifle soft and a few dealers are selling at as much as \$1 less than the average. Wholesale prices among the smaller producers went upward a bit with the increased demand. Steam sizes are moving fairly well, but there is a tendency toward a surplus again.

The weather at Baltimore has been so mild that consumption in homes has been negligible. Most of the yards are carrying fairly large stocks of anthracite, and there will be ample fuels to meet the first call that comes when genuine cold weather arrives.

At Buffalo the demand for anthracite is improving, but the weather is too mild for anything like a rush. Consumers look on the supply as pretty certain and if there is anything to be gained by waiting they want to be prepared to take advantage of it. The outlook does not favor much falling off in cost, but that is mostly on account of lack of enterprise. The coke trade is still quiet.

## Foreign Market And Export News

### Foreign Contracting Provides Only Bright Spot in British Market

Conditions in the Welsh steam coal trade are no worse, which is the very best that can be said of the present market. Enormous stocks are standing, and the Welsh pits are surrounded by huge mounds of small coals for which no buyers can be found.

Some interest is being shown in contracts for 1925, however. In addition to the French Midi contracts the Central Argentine Railways have placed an order for 300,000 tons of good admiralty large at about 26s., f.o.b., and the Entre Rios Ry. has placed an order for 50,000 tons on the same basis. The market is otherwise inactive, with prices fairly steady.

The owners' plea for a return to the 8-hour day has met with no response from the miners, whose co-operation would be necessary before the Act of Parliament authorizing such a change could be obtained. The attitude of the Welsh miners is to shorten the day still further, and frequent resolutions have been passed demanding a 6-hour day. The same attitude is maintained on the question of double shifts.

The Newcastle market is dull and weak. Prices have dropped a little, though there is a slightly improved inquiry for steam coals for winter shipment. Operators are hoping that the present abnormally low prices will encourage foreign buyers to clinch orders for early delivery.

Production by British collieries during the week ended Oct. 11, a cable to *Coal Age* states, was 5,088,000 tons, according to the official reports. This compares with 5,155,000 tons produced during the previous week.

### Trade Eases at Hampton Roads; Revival Expected

Business at Hampton Roads is slightly slower, with mild weather cutting down domestic trade with export movement at a minimum. New England is tak-

ing increasing quantities of coal and bunker trade is holding up well.

The market has weakened slightly, although supplies at tidewater are diminishing and dumpings at the coal piers are heavy. Retail business is good and prices are holding firm, with no prospect of reduction and a chance of increase in case forecasts of a severe winter are borne out.

The trade continues to be optimistic over the general situation and business is expectant of a general revival in activity.

### Less Life in Evidence in French Coal Market

The French industrial coal market shows little animation and business in house coal also is a little quieter, due to weather conditions. Shipments of sized products from Belgium are less active for the same reason.

The rise of sterling has increased the price of British coals, which were tending to attract more attention at the lower levels. British house and anthracite coals are neglected.

German coal deliveries on the open market continue small. The rolling stock position remains congested.

Deliveries of indemnity fuels during September to France and Luxemburg included 471,400 tons of coal, 437,800 tons of coke and 38,400 tons of lignite briquets, a total of 947,600 tons. This compares with 429,700 tons of coal, 425,800 tons of coke and 30,700 tons of lignite briquets, or a total of 886,200 tons of fuels, during the previous month.

Between Oct. 1 and 15 the O.R.C.A. received 144,603 tons of coke, a daily average of 9,660 tons.

With active British and French competition, the inquiry for industrial coals in the Belgian market is slack. House coals are steady but patent fuel and coke are depressed.

The strike is still on in the Borinage, but, the mine owners having signified their willingness to grant concessions, work is expected to be resumed soon.

### United States Domestic Coal Exports During September

## News Items From Field and Trade

### ALABAMA

The Pratt Fuel Corporation, of the Walter Moore Companies, Birmingham, has acquired the interests of the Grider Coal Co., including three mining operations, the Burnwell Coal Co., Yerkwood and others, \$500,000 being involved in the deal. It also is said that S. L. Yerkes will be in the Pratt Fuel Corporation. The Grider Coal Sales Agency is not affected by this deal, as it will continue as selling agency for the Pratt Fuel and the mines just taken over. The Walter Moore interests took over the Jagger and Nelson companies not long ago.

The Franklin Coal Mining Co. will begin the construction shortly of a Montgomery coal washer of large capacity to replace the old washery at its Powhatan Mine No. 2, which is not of sufficient capacity to handle the required tonnage from this operation. The improvements will cost approximately \$20,000. The Powhatan mines are located in the western section of Jefferson County in the Mary Lee seam and produced during 1923 about 250,000 tons of washed coal. The head offices of the company are in Birmingham.

### COLORADO

During September 935,364 tons of coal was mined in Colorado, compared with 863,500 tons mined in September 1923, bringing the total production for the first nine months of this year up to 7,221,707 tons compared with 7,345,599 tons mined during the same period last year. So far this year the number of days worked per mine in the state is 128.1. The total decrease in the production of coal during the first nine months of this year as compared with the corresponding period in 1923 has been 123,892 tons. During September 12,133 men were employed at the mines.

### ILLINOIS

Two Williamson County strip mines in the vicinity of Carterville have been reopened upon a full-time schedule. Weaver Mine No. 20 planned to resume operations about Oct. 25, after having been closed down since last November.

The Liberty Coal Co. with offices at 1206 Lehmann Building, Peoria, has installed a new coal cutter and a storage-battery locomotive. The company has ten trucks running between the mine and Peoria and is able to handle a large local business.

The Atwill Coal & Coke Co., McCormick Building, Chicago, has purchased

the entire assets and liabilities of the Atwill-Makemson Coal & Coke Co. J. L. Makemson retires from the business. F. C. Atwill remains as president of the company; H. L. Weith, vice-president, and J. B. Ullmen, secretary.

The Newcastle Coal Co., Edwardsville, has reopened its mine with twenty-five men working.

W. D. Obcamp has been elected a director of the Brewerton Coal Co. of Lincoln. James Casey, general superintendent of the mine, also has been elected to the board. Those on the board before these two names were added were: W. A. Brewerton, Roy O. West and Percy P. Eckhart. The board recently was increased from three men to seven, leaving two places to be filled, possibly by business men of Springfield and Lincoln.

William Y. Wildman, for years a traffic man for the Chicago & Northwestern R.R., has been made secretary of the Illinois Coal Traffic Bureau in Chicago, succeeding Frank H. Harwood, whose health has been precarious for some time and who must spend much of his time on his fruit farm in California.

The Kolb Coal Co. has opened its Mine No. 2, near Belleville, upon a full-time basis. This mine has been operating intermittently.

W. W. Austin, of Taylorville, has purchased the interests of J. M. Corine in the Decatur Coal Co., of Decatur, and will give his entire time to that work.

The Wenona Coal Co., Wenona, has leased its mine property to Edward L. Monser, vice-president of the company, and John Blazina, Marshall County mine inspector, who will operate it in partnership. The mine has been cleaned and is now ready for service.

The Shiloh mine of the Southern Coal & Mining Co., located near Belleville, has resumed operations after having been closed for six months. The mine employs 350 men. The Radium mine, employing 250 men, also has resumed operations.

Crescent Mine No. 1, in Marsh Creek Hollow, near Peoria, has begun operations on a half capacity basis after having been idle since March 29. This gives employment to about 250 men. With the opening of the Crescent Mine No. 1, about 40 per cent of the miners in the Peoria territory are now employed. This is an increase of 30 per cent over the total employed sixty days ago.

### INDIANA

The Brazil Collieries Co., of Brazil, has filed a preliminary certificate of dissolution with the Secretary of State of Indiana.

In the Indiana bituminous district 443,016 tons was produced by 189 mines during the week ending Oct. 11 as compared with 443,345 tons by 190 mines for the week previous. The 189 mines during the week ending Oct. 11 worked a total 3,461.34 hours and lost a total of 5,072.49 hours. Car shortage caused a loss of 59.66 hours; other railroad disability, 35.5 hours; labor troubles, 71.5 hours; mine disability, 625.25 hours; lack of orders, 4,280.58 hours. During the previous week lack of orders caused a time loss of 4,197 hours, or 49.54 per cent.

### IOWA

W. F. Moore, A. J. Harkins and Charles E. Moore have purchased the Liberty mine, located north of Des Moines, on the Twentieth Street road. The three men will operate the mine under the name of the Liberty Coal Co. and will do both a wholesale and retail business. They formerly owned and operated the Madison Coal Mining Co.

### KANSAS

An abandoned mine on Santa Fe land near Frontenac, in the Pittsburg field, has been leased by Albert Benelli and John Knoll, who have begun preparations to reopen it. The mine has a shaft to the coal, but the vein is only partly developed.

Despite a recent announcement by John L. Lewis, International president of the United Mine Workers, that Alexander Howat is ineligible for office in the organization, locals continue to send in his name for nomination for president of District 14 (Kansas). In one day recently seven locals placed his name in nomination.

### KENTUCKY

It has been reported at Madisonville that the Hart Coal Corporation, one of the big shaft mine operating companies of western Kentucky, will spend \$70,000 on a rescreening plant and in remodeling its tipples at the Victoria No. 11 mine and at the White City Mines. Improvements are to be completed within sixty days.

Two additional western Kentucky mines recently started operations on a non-union basis. One of these is the

Providence Coal Mining Co., of which Percy Berry is the head, the company starting with over 100 men on the waiting list. The Rockport Coal Co., operated by H. L. Tucker, at Centertown, also started operations, and with more men than it could use.

It is reported from Lexington, that Lexington and eastern capital is interested in a merger of coal mines and coal properties in Perry and Knott counties along Carrs Fork. J. P. Allen, of Lexington and Hazard, a large operator, is behind the movement, and slated to head the company if the merger is worked out. The Meem-Haskins Coal Co., Montgomery Creek Coal Co., Scuddy Creek Coal Co., and Carrs Fork Coal Co. are included in the merger plan.

Announcement was made at Lexington, Ky., Oct. 21, of purchase by L. W. Fields, of Lexington and Whitesburg, and the W. C. Belcher Land & Mortgage Co. of Ft. Worth, Texas, which has offices in Lexington, of a tract of several thousand acres of coal and timber land in Letcher County from the Mineral Development Co., of Philadelphia.

President Wes Ames of District No. 23, United Mine Workers, is urged in a communication sent him by County Attorney W. O. Smith, of Muhlenberg County to take immediate steps to adjust the differences between the union miners and operators of the district if he would save his organization from complete disruption. Mr. Smith formerly was president of District 23. He says three-fourths of the union miners of District 23 would go to work at a reduced wage if the union permitted it. Mr. Smith says he believes the policies of the international officers are wholly inapplicable to conditions in this section, and that they are using this territory to enrich that of the competitive field, which suffered from the same cause recently.

It was reported from Madisonville, Ky., on Oct. 22, that the West Kentucky Coal Co. had decided to abandon Mine No. 11, of the St. Bernard group, and that it would be sealed up. The mine was the first in Hopkins County, opened in 1870, and is largely responsible for development of the field and the establishment of the town of Earlington. The old mine has worked back so far in the hills that cost of transportation has become excessive.

The Court of Appeals of Kentucky, on Oct. 21, affirmed the Circuit Court dismissal of a petition of members of Union 3,348, District 19, United Mine Workers (southeastern Kentucky), to recover \$2 a day for each man, or a total of \$32,000, for an eighty-day

period in which they allege the Jellico Coal Co. arbitrarily closed down its mine and locked them out because they refused to surrender their charter. Failure to allege that notice had been given the company of fines to be assessed against the company rendered the petition invalid the court held.

## OHIO

Thomas H. Settle, general manager of the Virginia-Smokeless Coal Co., of Bluefield, was in Cincinnati recently consulting with engineers and others. He let it be known that another mine was being opened by his company and that production would be well on the way within a year.

Jewett, Bigelow & Brooks, through action of the receivers, closed their offices maintained on the sixth floor of the Dixie Terminal, Cincinnati, on Oct. 20. Only a small room on the same floor will be maintained by the receivers.

With Ben F. Ford at its head the Ford-Elkhorn Coal Co. has opened offices in the First National Bank Building, Cincinnati. Mr. Ford was long the directing partner of the Matthew Addy Co. in charge of its coal department prior to receivership proceedings. He is the owner of a mine or two in the Elkhorn district and has other valuable connections in that and other Kentucky districts.

Fire has broken out afresh in several new locations between New Straitsville and Shawnee in the big coal mine fire which has been raging in this territory for the past 40 years. Residents of New Straitsville are apprehensive that their homes may be undermined by the burning coal. It is estimated that more than 6,000 acres of good coal has been consumed in the last four decades.

The William S. Harman Coal Co. is gradually acquiring a considerable acreage around Philo, on the Muskingum River, and large developments will soon be made in that section. The company has obtained the contract to furnish the immense power plant of the American Gas & Electric Co., at that place with coal and the development will be made as the coal requirements increase. The power plant is one of the largest in the Middle West and already approximately \$25,000,000 has been spent in building it. Additional units are to be added later on. One of the first developments will be a large stripping operation.

A meeting of representatives of the Red Jacket Coal & Coke Co. was held recently at the general offices in Columbus with Ohio, Indiana, Michigan

and Canadian representatives in attendance. W. M. Ritter, chairman of the board of directors, and H. T. Wilson, president of the company, both gave talks. Sales manager Thomas H. Wilson had charge of the meeting. Following the conference all of the salesmen with I. D. Cooke, cashier, left to inspect the Red Jacket mines, where they were joined by W. H. Cummins, general superintendent; George Vance, superintendent, and J. F. Poindexter, who represents the company in Virginia and the Carolinas.

## PENNSYLVANIA

Wagon mines in the vicinity of the larger cities in the central Pennsylvania field are pushing operations and in many places cuts in prices of from 50c. to \$1 per ton have been made in order to get business. Many of the wagon mines are running full time and some two shifts.

At a primary election held in District No. 2, United Mine Workers, last week John Brophy for president, James Mark for vice-president and John Ghizzoni for national board member won over George Bassett, Jerre Ford and Evan Thomas, respectively, and will be elected at the general election in December. Mr. Brophy's total of locals placing him in nomination was 117 against 55 for Bassett; Mark carried 110 against Ford's 63 and Ghizzoni had 110 against 35 for Thomas.

The Mid Valley breaker of the Hazle Brook Coal Co., near Hazleton, has ceased operations and will be dismantled. Hereafter the tonnage of the mine will be hauled over the Lehigh Valley R.R. to the company's new breaker at Raven Run.

James L. Cooney, president of the Scranton Coal Co., Scranton, was recently tendered a banquet by men he played with and against in football 25 years ago, when he was a Princeton gridiron star. Harry Vaughn, former Yale player, was among those who turned out to honor the Scranton coal mining official.

Operation of the Wallwork mines at Mosgrove, near Kittanning, was resumed Oct. 20, after a recent suspension. The resumption gives employment to a number of men of the district. The mine was first opened in 1917, by Samuel Wallwork, who died a few weeks ago.

Three men were killed instantly in the Pittston vein of the No. 14 colliery of the Pennsylvania Coal Co., at Inkerman, when roof supports snapped while they were loosening a pillar stump and the roof fell, burying them beneath. The bodies were recovered by rescuers in about an hour's time.

Several operations in the Lehigh field which were idle during the summer months have resumed operations during the week and an increased tonnage is looked for by the Lehigh Valley R.R. The railroad and coal company managements are working to speed production to 20,000 tons a week as soon as possible and keep this up during the fall and winter, as the demand for fuel increases.

### Railroad Station, Rock Springs, Wyo.

In summer the only blue grass in town is grown in the station yard, and soil to grow that had to be brought from a ranch twelve miles away.

## UTAH

The arguments on motion of defendants to dismiss proceedings started by the federal government against the Carbon County Land Co. the Independent Coal & Coke Co. and Carbon County to recover title to 5,500 acres of alleged rich coal lands, were finished in Judge Tillman D. Johnson's court last week and the motion taken under advisement.
